ABSTRACT

The optimal treatment of non-Hodgkin lymphoma (NHL) in elderly patients is controversial. In this study, we evaluated the outcomes for elderly patients who were treated with combined chemotherapy regimens. Patients with lymphoma aged over 75 treated at our Cancer Institute between 2005 and 2014 were evaluated retrospectively. Demographic data were collected from 76 elderly lymphoma cases receiving Rituximab-Chemotherapy, Chemotherapy only or Rituximab only. Survival or death during treatment were recorded, and lengths of progression-free survival (PFS) and overall survival (OS) were calculated. Seventy-six elderly patients with lymphoma were enrolled, 51.4% (n= 39) male and 48.6% (n= 37) female. Median age at diagnosis was 79 (75-95) years. Histopathological examination revealed diffuse large B cell lymphoma (DLBCL) in 52% (n= 40) of patients, follicular lymphoma in 21% (n= 16), marginal zone lymphoma in 10.5% (n= 8), mantle cell lymphoma in 5.3% (n= 4), and T cell lymphoma in 9.2% (n= 7). Median PFS and median OS were 50.1 and 45.9 months, respectively. In this trial, PFS and OS levels in the high grade lymphoma were not significantly different from those in the low and intermediate grade groups (p= 0.16 and p= 0.49 respectively). Comorbidity did not have a significant effect on PFS or OS (p= 0.71 and p= 0.93). In conclusion, anthracyclin-based chemotherapy regimens are not significantly better than the others in terms of PFS (p= 0.32) and OS (p= 0.8). Survival outcomes of anthracyclin-based chemotherapy regimens in elderly lymphoma patients are similar to those of non-anthracycline-based chemotherapy regimens.

ÖZET

Yetmişbeş Yaş ve Üzeri Non-Hdgkin Lenfoma Hastalarında Antrasiklin Bazlı Kemoterapiler

Yaşlı hastalarda Non-Hodgkin lenfomanın (NHL) optimal tedavisi tartışmalıdır. Bu çalışmada kombine kemoterapiler uygulanan yaşlı NHL hastalarının tedavi sonuçları değerlendirildi. Kanser enstitümüzde 2005 ile 2014 yılları arasında tedavi edilen 75 yaş ve üstü lenfoma hastalarının retrospektif olarak değerlendirmesi yapıldı. Rituksimab-kemoterapi, sadece kemoterapi ve sadece Rituksimab alan 76 yaşlı lenfoma hastasının demografik verileri elde edildi. Tedavi sırasında sağkalım ve ölümler kaydedildi. Progresyonsuz sağkalım (PS) ve genel sağkalım (GS) süreleri hesaplandı. Toplam 76 lenfoma hastası kaydedildi. Hastaların %51.4'ü (n= 39) erkek, %48.6' s' i (n= 37) kadındı. Tanı anında ortalama yaş 79'du (75-95). Histopatolojik olarak hastaların %52' si (n= 40) diffüz büyük B hücreli lenfoma (DBBHL) iken, %21'i (n=16) folliküler lenfoma, %10.5' i (n= 8) marjinal zon lenfoma, %5.3 (n= 4) mantle hücreli lenfoma ve %9.2'si (n= 7) T-hücreli lenfoma histolojisine sahipti. Ortanca PS ve GS sırasıyla 50.1 ve 45.9 aydı. Yüksek dereceli lenfomaların PS ve GS değerleri, düşük ve orta dereceli gruplar ile karşılaştırıldığında anlamlı farklılık görülmedi (Sırasıyla p= 0.16 ve p= 0.49). Komorbitelerin PS ve GS üzerinde anlamlı etkisi yoktu (p= 0.71 ve p= 0.93). Sonuç olarak, antrasiklin bazlı kemoterapi rejimlerinin antrasiklin içermeyen rejimlere kıyasla anlamlı PS (p= 0.32) ve GS (p= 0.8) üstünlüğü yoktu. Yaşlı lenfoma hastalarında antrasiklin bazlı kemoterapi rejimleri ile antrasiklin içermeyen rejimlerinin sağkalım sonuçları benzerdi.

Anahtar Kelimeler: Yaşlı hasta, Lenfoma tedavisi, Antrasiklin

INTRODUCTION

The incidence rate of non-Hodgkin lymphoma (NHL) increases with advanced age and one-third of cases occur in patients ≥ 70 years of age.¹ Age is one of the most important prognostic factor.² In elderly patients with diffuse large B-cell subtype, overall survival decreases with age.^{2,3}

The most effective management strategies and chemotherapy regimens for elderly patients have still controversial. Although NHL can be effectively treated with aggressive combined chemotherapy regimens, advanced age may be an obstacle for aggressive treatment. Decreased hematological reserve, reduced performance status, decreased drug metabolism, and comorbid diseases such as decreased left ventricle ejection fraction, hepatic or renal impairment may affect to choose treatment regimen in elderly patients.

Anthracycline is one of the cornerstones of therapy for lymphoma and is used as combine with other chemotherapy drugs. Higher response rate and improved overall survival were achieved in elderly patients with diffuse large B-cell lymphoma who were treated with anthracycline-containing chemotherapy regimens compared to those who received non-anthracycline chemotherapy regimens.⁴ However, cardiac toxicity is the most important life-treating adverse effect of anthracycline. The risk of cardiotoxicity of anthracyclines may limit the use in elderly patients.

In this study, we aimed to evaluate efficacy of anthracycline and non-anthracycline-containing regimens in ≥ 75 years patients with NHL.

PATIENTS AND METHODS

In this study we retrospectively evaluated the treatment options and their results in elderly patients with non-Hodgkin lymphoma who were treated at the Hacettepe University Faculty of Medicine, Turkey, between 2005 and 2014. Demographic data were collected from 76 elderly lymphoma cases with older than 75 years (age, sex, comorbidity, Aestern Cooperative Oncology Group (ECOG) performance status, stage, presence of B symptoms, serum lactat dehydrogenase (LDH) levels, presence of extranodal disease and bone marrow involvement. Also, histological subtype of lym-

phoma, used with treatment regimens and response to treatment were recorded.

Response to chemotherapy was evaluated after 3 cycles, or following discontinuation of the planned treatment. Thereafter, clinical examination was performed every 3 months for the first 2 years, and then every 6 months for 3 years. A neck, chest, and abdominal computed tomographic scan were performed after 6 months, and then every 6 months during the first 5 years. After 5 years, clinical examination was performed once a year.

Complete remission (CR) was defined as disappearance of all target lesions and a decrease in the short axis measurement of all pathological lymph nodes to ≤ 10 mm. Partial response (PR) was defined as a 30% decrease in measurable tumor mass after treatment, with no new areas of tumor development and no tumor area exhibiting progression. Progression (PD) was defined as a $\geq 20\%$ increase of at least 5 mm in the sum of the longest diameters of the target lesions compared with the smallest sum of the longest diameter recorded or the appearance of new lesions including those detected by fludeoxyglucose-positron emission tomography (FDG-PET). Stable disease was defined as measurable tumor not meeting the criteria for either PR or PD (RECIST guideline, version 1.1).

Statistical Analysis

Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 15.0. Statistical analyses were two-way, and $p < 0.05$ was considered statistically significant. Chi-square test was used to demonstrate differences between nominal and ordinal variables. Mann-Whitney U test and Wilcoxon test were used to analyse differences between independent variables, and Student's-t test was used to evaluate numerical variables with normal distribution. Overall and progression-free survivals were analyzed by the Kaplan-Meier.

RESULTS

Seventy-six elderly lymphoma patients were included in the study. At the time of diagnosis, the median age was 79 years (75-95). Mean follow-up period was 29 months. Patients' demographic data are given in Table 1 and Table 2.

14). Serum β 2- microglobulin levels were elevated in 44% and LDH levels in 91% of the patients. Treatment modalities are shown in Table 3.

Tumor Characteristics and Treatment Modalities

Histopathological examination revealed diffuse large B cell lymphoma (DLBCL) in 52% (n= 40) of patients, follicular lymphoma in 21% (n= 16), mantle cell lymphoma in 5.3% (n= 4), marginale zone lymphoma in 10.5% (n= 8), T cell lymphoma in 9.2% (n= 7) and 1.3% (n= 1) non-classified low grade NHL. Patients were generally diagnosed with advanced stage disease. Stage III disease was recorded in 35% of DLBCL patients and 27% of follicular lymphoma patients.

Forty-five percent (n= 17) of DLBCL patients and 75% (n= 3) of mantle cell lymphoma patients received rituximab-cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP) therapy. T cell lymphoma patients mostly received CHOP therapy. Eighty-seven percent (n= 14) of follicular lymphoma patients received regimens such as rituximab (R), rituximab-cyclophosphamide (R-C) and rituximab-cyclophosphamide, vincristine,

prednisone (R-CVP). The majority, 71%, of marginal zone lymphoma patients received non-adriamycin-based therapies.

Survival

The median progression free survival (PFS) was 50.1 months. No difference in PFS was determined between aggressive and indolent lymphomas (p= 0.16). No difference in PFS was also detected between male and female genders (p= 0.80).

Analysis of the effect of the patients’ characteristics on PFS revealed no difference in ECOG in terms of time of diagnosis (p= 0.15), stage (p= 0.98), presence of B symptoms (p= 0.57), bone marrow involvement (p= 0.87), extranodal disease (p= 0.85), presence of anemia (p= 0.20), presence of lymphopenia (p= 0.42), elevated B2 microglobulin (p= 0.24) or sedimentation (p= 0.28). Comorbidity (p= 0.71) and comorbidity requiring treatment (p= 0.27) had no effect on PFS. Investigation of

Table 4. Terms of survivals for each of the disease and the treatment groups

Parameters	Antra-cycline	Non-antra cycline	P value
Indolent NHL			
PFS (months)	50.2	38.3	0.46
OS (months)	66.2	46.9	0.27
Aggressive NHL			
PFS (months)	49.6	34.0	0.33
OS (months)	61.7	42.8	0.40
Overall			
PFS (months)	49.8	36.6	0.67
OS (months)	65.1	43.2	0.80

OS: Overall survival

the effect of chemotherapy on PFS revealed that receipt of adriamycin-based or non-adriamycin-based therapy had no effect on PFS (p= 0.32). Radiotherapy also had no effect on PFS (p= 0.29).

The median OS was 45.9 months. No difference in OS was determined between aggressive and indolent lymphomas (p: 0.49). Examination of patient characteristics revealed no significant effect on OS of stage of disease (p= 0.14), presence of B symptom (p=0.14), extranodal disease (p= 0.71), presence of lymphopenia (p= 0.40), B2 microglobulin elevation (p= 0.39), sedimentation (p= 0.30) or gender (p= 0.39). Examination of comorbidity (p= 0.93) and comorbidity requiring treatment (p= 0.96) also identified no effect on OS. ECOG performance status (p= 0.01), bone marrow involvement (p= 0.02) and presence of anemia at the baseline (p= 0.01) had a significant effect on OS.

Investigation of the effect of chemotherapy on OS revealed that anthracyclin-based chemotherapy had no effect on OS (p= 0.80). Mean survival of patients receiving anthracyclin-based therapy was 65 months, compared to 43 months in those receiving nonanthracyclin-based therapy (p= 0.80). Radiotherapy had no effect on OS (p= 0.45). The survival data are shown in Table 4.

DISCUSSION

At diagnosis, most of our patients had good performance status, comorbidity (one or more), B symptoms had a high LDH level (91%), mostly extranodal disease and many were in an advanced stage. Serum B2 microglobulin levels were elevated in 44% of the patients. Median age at the diagnosis was 79 years (75-95).

The standard treatment of non-Hodgkin lymphoma (NHL) in elderly patients is still controversial. Age is known to be an adverse prognostic factor in all subtypes of NHL.⁵ At advanced age, other factors (e.g., comorbidity and functional status), in addition to age and PS may play an important role in determining the survival of NHL patients.⁶ Clinical studies in elderly NHL patients have shown the negative impact of comorbidity on prognosis.⁷⁻¹² There has been little investigation of the relevance of functional status and/or comorbidity in elderly patients with NHL. ECOG performance status was 0-1 in 57.8% (n= 44) of our study group. When ECOG was compared, a difference was observed on OS (p: 0.01). A difference on OS was also determined in the presence of anemia, which significantly affects performance status (p= 0.01). In addition, no effect was determined on PFS or OS in patients with comorbidity or comorbidity requiring treatment (p= 0.71 and p= 0.27) (p= 0.93 and p= 0.96).

Three large phase III, randomized, prospective clinical trials and a large population registry in the Netherlands have shown that DLBCL is significantly more frequent among elderly patients, in contrast to follicular lymphoma.^{3,5,13,14} DLBCL comprised the majority of the cases in our study group (50% patients, n= 40) too.

Patients with disseminated high-grade extranodal NHL have been shown to exhibit the poorest prognosis.¹⁵ Extranodal involvement mostly spleen and bone marrow were observed in 50% (n= 39) of our patients (Bone marrow involvement in 18.4%, n= 14). Moreover, in Carbone et al.'s study, 52% of NHL cases were extranodal at presentation, and the gastrointestinal tract was the most frequently involved site (47.3%).¹⁶ D'Amore et al. reported that extranodal presentation, particularly involving the stomach and bone marrow.¹⁷ Finally, extranodal disease was determined in approximately 40%

of patients with NHL aged over 80 in two institutions.¹⁸

In our study median length of follow-up was 29 months. Median PFS was 50.1 months and median OS 45.9 months. No difference was determined in PFS (p= 0.16) or OS (p= 0.49) between aggressive and indolent lymphomas (p= 0.49). Opposite to this, Bairey O et al. revealed that patients with indolent lymphomas had a significantly better 3-year survival and median survival than those with aggressive lymphomas.¹

The most appropriate treatment for elderly patients with lymphoma is the subject of debate. Standard regimens may not be possible for reasons such as comorbidity, performance status, using other drugs and social support. In our study 45% (n= 17) of DLBCL patients and 75% (n= 3) of mantle cell lymphoma patients received R-CHOP and T cell lymphoma patients mostly received CHOP therapy. Eighty-seven percent (n= 14) of follicular lymphoma patients received regimens such as R, R-C and R-CVP. The majority, 71%, of marginal zone lymphoma patients received non-adriamycin-based therapies. Investigation of the effect of chemotherapy on PFS revealed that receipt of anthracyclin-based or non-anthracyclin-based therapy had no effect on PFS (p= 0.32). Also investigation of the effect of chemotherapy on OS revealed that anthracyclin-based therapy had no effect on OS (p= 0.80). Mean survival of patients receiving anthracyclin-based therapy was 65 months, compared to 43 months in those receiving nonanthracyclin-based therapy (p= 0.80). Radiotherapy had no effect on PFS and OS (p= 0.29, p= 0.45).

In a study from 2001, Tirelli U et al. described the CHOP regimen as the standard therapy in patients with stage II-III lymphoma aged 70 or above.¹⁹ In another retrospective study, Grogan L et al. the patients received similar regimens with the same chemotherapy dose intensity, irrespective of age.²⁰ Standard-dose m-BACOD (methotrexate, bleomycin, adriamycin, cyclophosphamide, vincristine and prednisone) or CHOP were used to treat elderly patients and patients < 65. The 3-year OS and 3-year PFS of patients > 65 years (58%) were not significantly different from those of patients < 65 years (65%) treated with the same regimen.

Randomized phase III clinical studies have compared the CHOP and CNOP regimens in elderly lymphoma patients and reported significantly better OS and disease-free survival in patients treated with CHOP than in those receiving CNOP.^{21,22} In contrast to those results, analysis of the effect on survival of chemotherapy regimens that adriamycin-based or not had no effect on PFS ($p=0.32$) and OS ($p=0.80$) in our study. Also in Davis CC et al. study there was no statistically significance in PFS or OS for patients who received adriamycin containing chemotherapy and those who did not. Interestingly, tolerability was similar between the two treatment groups.²³

This may be attributed to the varying grades of disease in our NHL group. We think that patients should receive a standard regimen if their performance status and any comorbid diseases are appropriate. However, the elderly patient group received a lower dose than the younger patient group. The biological and immunological characters of NHL in the elderly patient group are unclear, and since this group is not generally included in clinical studies, treatment-related difficulties persist.
