The molecule of the title compound, $C_{16}H_{17}N_5O_3$, is build up from two fused six-membered rings linked to a 1,2,3-triazole ring, which is attached to an ethyl azido-acetate group. The dihydroquinoxalinone portion is planar to within 0.0512 (12) Å and is oriented at a dihedral angle of 87.83 (5)° with respect to the pendant triazole ring. In the crystal, a combination of intermolecular C—H···O and C—H···N hydrogen bonds together with slipped π -stacking [centroid–centroid distance = 3.7772 (12) Å] and C—H··· π (ring) interactions lead to the formation of chains extending along the *c*-axis direction. Additional C—H···O hydrogen bonds link these chains into layers parallel to the *bc* plane and the layers are tied together by complementary π -stacking [centroid–centroid distance = 3.5444 (12) Å] interactions. The Hirshfeld surface analysis of the crystal structure indicates that the most important contributions for the crystal packing are from H···H (44.5%), H···O/O···H (18.8%), H···N/N···H (17.0%) and H···C/C···H (10.4%) interactions.

1. Chemical context

Quinoxaline derivatives, especially quinoxalinone, are of great importance in medicinal chemistry (Ramli & Essassi, 2015; Ramli *et al.*, 2017) and can be used for the synthesis of numerous heterocyclic compounds with various biological activities such as antibacterial (Griffith *et al.*, 1992), HIV (Loriga *et al.*, 1997), antimicrobial (Badran *et al.*, 2003), anti-inflammatory (Wagle *et al.*, 2008), antiprotozoal (Hui *et al.*, 2006), and anticancer (Carta *et al.*, 2006). In a continuation of our research work devoted to the study of cycloaddition reactions involving quinoxaline derivatives (Ramli *et al.*, 2011, 2013; Abad *et al.*, 2018; Sebbar *et al.*, 2016), we report in this work the synthesis, using 3-methyl-1-(prop-2-ynyl)-3,4-dihydroquinoxalin-2(1*H*)-one as dipolarophile and ethyl azido acetate as 1,3-dipole, and crystal structure of ethyl 2-{4-[(3-methyl-2-oxo-1,2-dihydroquinoxalin-1-yl)methyl]-1*H*-1,2,3-triazol-1-yl}acetate, $C_{16}H_{17}N_5O_3$ (Fig. 1).

2. Structural commentary

The molecule of the title compound is build up from two fused six-membered rings linked to a 1,2,3-triazole ring which is attached to ethyl azidoacetate group (Fig. 1) (Sebbar *et al.*, 2014; Ellouz *et al.*, 2015).

Atoms C8 and N2 are displaced from the mean plane through the dihydroquinoxalinone unit by 0.0367 (13) and -0.0512 (12) Å, respectively, with the remaining atoms within 0.0222 (15) Å of the plane (r.m.s deviation of the fitted atoms is 0.0234 Å). The pendant triazole ring is inclined to this plane by 87.83 (5)°.

3. Supramolecular features

Hydrogen bonding and van der Waals contacts are the dominant interactions in the crystal packing. In the crystal, $C-H_{Dhyqnx}\cdots O_{Ethazac}$, $C-H_{Ethazac}\cdots O_{Dhyqnx}$, $C5-H_{Dhyqnx}\cdots N_{Ethazac}$ and $C-H_{Trz}\cdots N_{Dhyqnx}$ ($Dhyqnx$ = dihydroquinoxalin, Ethazac = ethyl azidoacetate and Trz = triazol) hydrogen bonds (Table 1) form chains extending along the c -axis direction (Figs. 2 and 3). These are reinforced by slipped π -stacking interactions between inversion-related A ($N1/N2/C1/C6-C8$) rings [centroid–centroid distance = 3.7772 (12) Å] and by complementary $C-H_{Dhyqnx}\cdots Cg3$ interactions [$Cg3$ is the centroid of the benzene ring B ($C1-C6$)] (Table 1 and Fig. 2). The chains are linked into layers parallel to the bc plane by sets of four $C-H_{Dhyqnx}\cdots O_{Ethazac}$ hydrogen bonds (Table 1 and Fig. 3) with the layers linked along the a -axis direction by inversion-related slipped π -stacking interactions between the A and B rings [centroid–centroid distance = 3.5444 (12) Å] (Fig. 2).

**Figure 4**

View of the three-dimensional Hirshfeld surface of the title compound plotted over d_{norm} in the range -0.2685 to 1.3470 a.u.

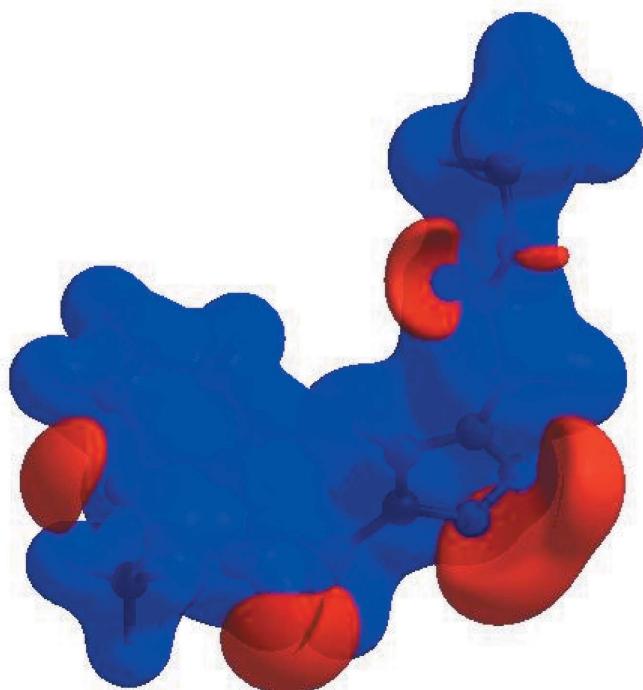

4. Hirshfeld surface analysis

Visualization and exploration of intermolecular close contacts in the crystal structure of the title compound is invaluable. Thus, a Hirshfeld surface (HS) analysis (Hirshfeld, 1977; Spackman & Jayatilaka, 2009) was carried out by using *CrystalExplorer17.5* (Turner *et al.*, 2017) to investigate the

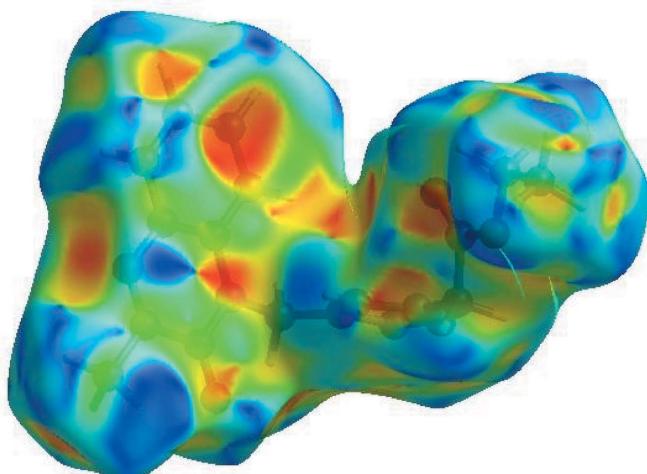

locations of atom–atom short contacts with the potential to form hydrogen bonds and the quantitative ratios of these interactions as well as those of the π -stacking interactions. In the HS plotted over d_{norm} (Fig. 4), the white surface indicates contacts with distances equal to the sum of van der Waals radii, while the red and blue colours indicate distances shorter (in close contact) or longer (distinct contact) than the van der Waals radii, respectively (Venkatesan *et al.*, 2016). The bright-red spots appearing near O1, O2, N1, N3 and hydrogen atoms H5, H4, H9B and H12 indicate their roles as the respective donors and acceptors in the dominant C–H \cdots O and C–H \cdots N hydrogen bonds; they also appear as blue and red regions corresponding to positive and negative potentials on the HS mapped over electrostatic potential (Spackman *et al.*, 2008; Jayatilaka *et al.*, 2005) shown in Fig. 5. The blue regions indicate positive electrostatic potential (hydrogen-bond donors), while the red regions indicate negative electrostatic potential (hydrogen-bond acceptors).

The shape-index of the HS is a tool to visualize π – π stacking interactions by the presence of adjacent red and blue triangles; if there are no adjacent red and/or blue triangles, then there are no π – π interactions. Fig. 6 clearly suggest that there are π – π interactions present in the title compound.

The overall two-dimensional fingerprint plot is shown in Fig. 7*a* and those delineated into H \cdots H, H \cdots O/O \cdots H, H \cdots N/N \cdots H, H \cdots C/C \cdots H, C \cdots C, N \cdots C/C \cdots N, O \cdots C/C \cdots O and N \cdots N contacts (McKinnon *et al.*, 2007) are illustrated in Fig. 7*b–i*, respectively, together with their relative contributions to the Hirshfeld surface. The most important interaction is H \cdots H contributing 44.5% to the overall crystal packing, which is reflected in Fig. 7*b* as widely scattered points of high density due to the large hydrogen content of the molecule. The wide peak in the centre at $d_e = d_i = 1.18$ Å in Fig. 7*b* is due to the short interatomic H \cdots H contacts (Table 2). In the fingerprint plot delineated into H \cdots O/O \cdots H contacts Fig. 7*c*, the 18.8% contribution to the HS arises from the intermolecular C–H \cdots O hydrogen bonding (Table 1)

**Figure 5**

View of the three-dimensional Hirshfeld surface of the title compound plotted over electrostatic potential energy in the range -0.0500 to 0.0500 a.u. using the STO-3 G basis set at the Hartree–Fock level of theory. Hydrogen-bond donors and acceptors are shown as blue and red regions around the atoms, corresponding to positive and negative potentials, respectively.

Symmetry codes: (i) $-x+1, -y+1, -z$; (ii) $x-1, y-1, z$; (iii) $-x+1, -y+2, -z+1$; (iv) $-x+1, -y+1, -z+1$; (v) $x-1, y, z$; (vi) $-x+2, -y+2, -z$; (vii) $-x, -y+1, -z+1$; (viii) $-x, -y+1, -z$; (ix) $x, y, z-1$; (x) $x, y+1, z$.

besides the H \cdots O/O \cdots H contacts (Table 2) and is viewed as pair of spikes with the tips at $d_e + d_i \sim 2.27 \text{ \AA}$. The H \cdots N/N \cdots H contacts in the structure with 17.0% contribution to the HS have a symmetrical distribution of points, Fig. 7d, with the

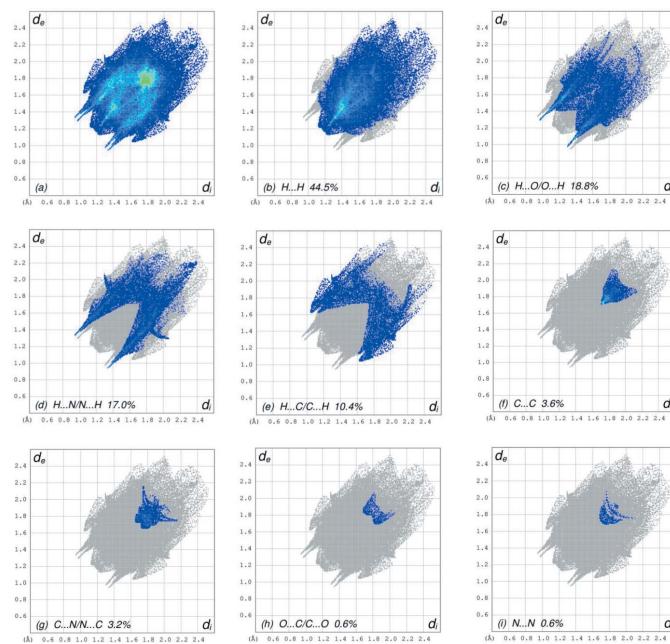

Figure 7

The full two-dimensional fingerprint plots for the title compound, showing (a) all interactions, and delineated into (b) H \cdots H, (c) H \cdots O/O \cdots H, (d) H \cdots N/N \cdots H, (e) H \cdots C/C \cdots H, (f) C \cdots C, (g) C \cdots N/N \cdots C, (h) O \cdots C/C \cdots O and (i) N \cdots N interactions. The d_i and d_e values are the closest internal and external distances (in \AA) from given points on the Hirshfeld surface contacts.

tips at $d_e + d_i \sim 2.30 \text{ \AA}$ arising from the short interatomic C \cdots H \cdots N hydrogen bonding (Table 1) as well as from the H \cdots N/N \cdots H contacts (Table 3). The presence of a weak C \cdots H \cdots π interaction (Table 1) results in two pairs of characteristic wings in the fingerprint plot delineated into H \cdots C/C \cdots H contacts with a 10.4% contribution to the HS, Fig. 7e, while the two pairs of thin and thick edges at $d_e + d_i \sim 2.77$ and 2.67 \AA , respectively, result from the interatomic H \cdots C/C \cdots H contacts (Table 2). The interatomic C \cdots C contacts (Table 2) with a 3.6% contribution to the HS appear as an arrow-shaped distribution of points in Fig. 7f, with the vertex at $d_e = d_i = 1.71 \text{ \AA}$. Finally, the C \cdots N/N \cdots C (Fig. 7g) contacts (Table 3) in the structure, with a 3.2% contribution to the HS, have a symmetrical distribution of points, with a pair of wings appearing at $d_e = d_i = 1.67 \text{ \AA}$. The Hirshfeld surfaces mapped over d_{norm} plotted are shown for the H \cdots H, H \cdots O/O \cdots H, H \cdots N/N \cdots H, H \cdots C/C \cdots H, C \cdots C and C \cdots N/N \cdots C interactions in Fig. 8a-f, respectively.

The Hirshfeld surface analysis confirms the importance of H-atom contacts in establishing the packing. The large number of H \cdots H, H \cdots O/O \cdots H, H \cdots N/N \cdots H and H \cdots C/C \cdots H interactions suggest that van der Waals interactions and hydrogen bonding play the major roles in the crystal packing (Hathwar *et al.*, 2015).

5. Synthesis and crystallization

To a solution of 3-methyl-1-(prop-2-ynyl)-3,4-dihydroquinoxalin-2(1H)-one (0.65 mmol) in ethanol (20 mL) was added ethyl azidoacetate (1.04 mmol). The mixture was stirred under reflux for 24 h. After completion of the reaction (monitored by TLC), the solution was concentrated and the residue was purified by column chromatography on silica gel by using as eluent a hexane/ethyl acetate (9/1) mixture. Crystals were obtained when the solvent was allowed to evaporate. The solid product isolated was recrystallized from ethanol to afford yellow crystals in 75% yield.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. H atoms were located in a difference-Fourier map and were refined freely. Eleven reflections appearing near the top of the frames on which they were recorded were omitted from the final refinement as they appeared to have been partially obscured by the nozzle of the low-temperature attachment.

Special details

Experimental. The diffraction data were collected in three sets of 363 frames (0.5° width in ω) at $\varphi = 0, 120$ and 240° . A scan time of 40 sec/frame was used. Analysis of 226 reflections having $I/\sigma(I) > 12$ and chosen from the full data set with *CELL_NOW* (Sheldrick, 2008) showed the crystal to belong to the triclinic system and to be twinned by a 176° rotation about the real axis $1,-0.8,-0.11$. The raw data were processed using the multi-component version of *SAINT* under control of the two-component orientation file generated by *CELL_NOW*.

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F, with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\text{sigma}(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R-factors based on ALL data will be even larger. Refined as a 2-component twin.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters (\AA^2)

Symmetry codes: (i) $-x+1, -y+1, -z$; (ii) $x-1, y-1, z$; (iii) $-x+1, -y+2, -z+1$; (iv) $-x+1, -y+1, -z+1$; (v) $x-1, y, z$; (vi) $-x+2, -y+2, -z$; (vii) $-x, -y+1, -z+1$; (viii) $-x, -y+1, -z$; (ix) $x, y, z-1$; (x) $x, y+1, z$.

Hydrogen-bond geometry (\AA , °)

Cg3 is the centroid of the benzene (C1—C6) ring.

$D\cdots H\cdots A$	$D\cdots H$	$H\cdots A$	$D\cdots A$	$D\cdots H\cdots A$
