ABSTRACT: The oral application of drugs is the most popular route for achieving systemic effects, nevertheless, it is limited by difficulties related to physicochemical properties of the drug. Solid lipid nanoparticles (SLNs) are appealing extensive notice because of showing increased solubility and improved oral bioavailability via different mechanisms. The aim of the study is to compare and peruse the *in-situ* permeation of nebivolol (NBV) loaded SLN and its commercial tablet formulation used for the treatment of hypertension. For this aim Single-Pass Intestinal Perfusion (SPIP) method was used for *in-situ* permeation studies. NBV loaded SLNs were prepared and modified with polyethylene glycol (PEG). In order to prepare SLNs by homogenization technique, compritol, lecithin and poloxamer were chosen. Particle sizes of blank and loaded SLN were 213.4±17.5 and 264.1±18.8 nm, respectively with polydispersity index values of approximately 0.3 for each. NBV loading resulted in positive electrical charge on SLNs. The encapsulation efficiency was 98.04±0.2 %. Permeability coefficient values were tripled when NBV was incorporated in SLNs and doubled when pure NBV was given separately with a blank SLN. PEG modified SLN can be used to enhance oral absorption of NBV, and SLNs alone can be used as permeation enhancer in oral drug delivery..

KEYWORDS: Solid lipid nanoparticle; nebivolol; segmental permeability; intestinal absorption.

1. INTRODUCTION

Hypertension, which is high blood pressure, can be counted as a main risk factor for cardiovascular diseases. Studies showed that there is a direct relationship between cardiovascular diseases such as stroke and coronary artery disease and the level of the high blood pressure [1, 2]. The use of beta adrenergic receptor blockers is taking attention as first-line treatment of all types of arterial hypertension [3, 4].

Nebivolol (NBV) is a third generation cardioselective beta 1-blocker which provides combination of beta-adrenergic blocking activity and vasodilation. Furthermore, NBV can be used for the treatment of angina cordis and congestive heart failure as an addition to its usage as an antihypertensive agent [5]. This active substance, indeed, is currently being chosen for treatment of arterial hypertension because the way it reduces the blood pressure via vasodilatory properties mediated by the l-arginine/NO pathway [4, 6]. Currently, 10 mg oral tablet form of NBV is available on the market.

Oral route is the most favored route for drug administration due to ease of application with high patient compliance. Nevertheless, in oral drug delivery there is a need for innovative drug delivery systems due to low drug solubility, poor gastrointestinal absorption, metabolism related variability issues, continuous fluctuation of drug plasma levels and food effects [7, 8]. Nebivolol is absorbed rapidly after oral administration and is not affected by food; however, it has variable absolute oral bioavailability due to its extensive first-pass metabolism [9]. Due to the low aqueous solubility and high membrane permeability, NBV is categorized as a Class II drug according to Biopharmaceutics Classification System [10]. Therefore, in

How to cite this article: Gokce EH, Kaynak MS, Yurdasiper A, Ustundag-Okur N, Sahin S. Comparison of intestinal permeability of nebivolol hydrochloride loaded solid lipid nanoparticles with commercial nebivolol tablet. Marmara Pharm J. 2018; 22 (4): 578-586.

order to overcome the problems seen by conventional NBV tablets, an efficient oral drug delivery system is needed.

In order to increase the oral bioavailability, colloidal systems, especially nanoparticles are of particular importance. In case of nanoparticles, bioavailability depends on the properties of the nanocarrier instead of physicochemical properties of the drug [11-13]. Recently, solid lipid nanoparticles (SLNs) have increased attention due to their inimitable structure and properties, such as improved biocompatibility, high bioavailability, protection for the incorporated drug against degradation, and controlled release of drugs [14, 15]. As carriers, the artificial or natural synthetic solid lipids were used to obtain solid colloidal particles [16, 17]. SLNs are able to increase the bioavailability of lipophilic and poorly hydrophilic drugs. An antihypertensive drug nitrendipine's low oral bioavailability (10 to 20%) was increased up to three- to four fold compare to that of a nitrendipine suspension, when formulated as SLN [18]. Beside these advantages, surface modification of SLNs with polyethylene glycol (PEG) lead to a developed surface hydrophilicity of nanoparticles which emerged improved transmucosal transport for drug delivery [19].

In oral delivery, the main absorption takes place in the small intestines, and absorption of drugs designed for oral applications could be different in duodenum, jejunum, and ileum. [20, 21]. In the formulation development, knowing the absorption site and absorption characteristics of active ingredient is important [22]. Since intestinal transit time is about 3-4 hours, it can be accepted as that the absorption of the drug is high in the entire intestine. In the light of this knowledge, for identification of development strategies of nanoparticulate formulations, absorption properties in the all intestinal tract with low solubility and/or low permeability drugs have a significant importance [23].

The main objective of the study was to compare and evaluate the *in-situ* permeation of NBV loaded SLN and its commercial tablet used for the treatment of hypertension. NBV loaded and PEG modified SLNs were developed to increase NBV's oral bioavailability. In order to prepare SLNs by homogenization technique, Compritol, lecithin and poloxamer were selected. For this aim, Single-Pass Intestinal Perfusion (SPIP) method was used for *in-situ* permeation studies [21-25].

2. RESULTS AND DISCUSSION

In this study, SLNs were produced and evaluations were performed to determine the permeability characteristics of NBV as pure powder, in tablet and SLN formulations across the gastrointestinal tract.

2.1. Preparation and characterization of SLNs

NBV loaded SLNs were prepared by using high shear mixing followed by high pressure homogenization at 500 bars for 1 cycle. The characterization studies of the blank and NBV loaded SLNs were performed by measuring the particle size, polydispersity index (PDI), encapsulation efficiency and zeta potential.

Particle size distribution at nano level is very important for bioavailability enhancement in oral drug delivery. Particle size of unloaded SLN was 213.4 ± 17.5 nm. Loading NBV into SLNs made a significant increase in particle size (264.1 ± 18.8 nm) ($p < 0.05$).

Another important parameter is the measurement of PDI because these carriers are polydisperse in nature. PDI values between 0 - 0.3 are monodisperse and homogeneous, but more than 0.3 is an indicator of non-homogeneity and Polydispersity [26]. PDI values obtained for blank and NBV loaded SLNs were 0.318 ± 0.05 and 0.309 ± 0.05 , respectively.

A specific result was observed for zeta potential, since NBV gave a positive charge effect on SLNs. Addition of NBV changed zeta potential from approximately -32 mV to almost neutral (-0.3 mV).

To calculate the entrapment efficiency of NBV, ultracentrifugation method was used. The encapsulation efficiency was found as $98.04 \pm 0.2\%$, indicating the suitability of the formulation for NBV incorporation.

These results showed that NBV can be successfully encapsulated in SLNs with a high yield as a homogeneous distribution with the method employed in our study.

A detailed paper has been published about preparation, characterization, *in vitro* release and pharmacokinetic studies about NBV-SLNs by our team [17]. This study mainly focuses on *in-situ* permeation studies via SPIP method.

2.2. Permeability studies

Metoprolol tartrate was used as a marker for the integrity of the experiment, and phenol red as a non-absorbable marker in all groups. In order to determine NBV permeability, it is co-perfused with metoprolol tartrate, simultaneously. Results showed that permeability (P_{eff}) was 0.895 ± 0.3 cm/sec for metoprolol tartrate and 0.772 ± 0.2 cm/sec for NBV. P_{eff} values calculated for NBV following perfusion of ileum are shown in Figure 1.

The highest P_{eff} and k_a value was obtained with NBV-SLN and the least permeable forms were tablet and pure drug (Table 1). Net water flux (NWF) values indicated the water secretion into segment by pure NBV (24.07 mL/h/cm) and pure NBV administered together with blank SLN. A loss of fluid was observed from segment for NBV loaded SLN (-21.43 mL/h/cm) and NBV tablet (-22.7 mL/h/cm) administered groups. Yang et al. reported that the absorptive clearance values estimated for compounds from in situ perfusion studies is based on loss from the intestinal lumen, and require correction of effluent concentration with NWF. For a low permeability drug, an absorptive clearance estimated from a non-linear equation approaches to a linear relationship with NWF regardless of whether NWF has a real effect on absorptive clearance [27].

The increment in P_{eff} and k_a was expected with NBV incorporation in SLNs. One study showed that loading andrographolide (antilipidemic drug) into SLNs enhanced the bioavailability of the drug as 241%, compared to the drug's suspension [28]. Similarly, the SLN formulation increased the relative bioavailability of oxyresveratrol by 125% when compared with unformulated drug [29]. Our results were in accordance with these findings. P_{eff} of NBV was increased by about 294 % in our study, as expected. Moreover, it was surprising to find out that P_{eff} of NBV was doubled, when pure NBV and blank SLN were given together (Table 1). This result points out that SLN does not only serve as a colloidal matrix for encapsulated drugs but also acts like a permeation enhancer in oral drug delivery.

There are several possible mechanisms to explain the enhanced permeability/bioavailability of drugs given in nano-lipid carriers; such as i) maintaining a solubilized state of the drugs in the GI tract, ii) formation of mixed micelles, iii) promoting the secretion of endogenous phospholipids and bile salts [30]. These mechanisms might be used to explain the enhanced absorption obtained with NBV loaded SLNs. On the other hand, the increment in P_{eff} of the pure drug with SLN might be attributed to the muco-penetrating ability of SLN, and the enhanced intestinal lymphatic lipid flux. During this lipid flux pure drug absorption might be stimulated

Table 1. Absorption rate constant (k_a) of metoprolol tartrate and NBV across rat ileum.

Formulation	Rat intestinal absorption rate constant, k_a ($\times 10^{-4}$, 1/sec)
MTP	$9.72 \pm 3.5^*$
NBV	$6.65 \pm 3.0^*$
NBV + unloaded SLN	8.98 ± 3.1
NBV loaded SLN	13.00 ± 3.2
NBV (in tablet)	$6.39 \pm 3.0^*$

* $p < 0.05$ as compared to "NBV loaded SLN"

Figure 1. The permeability coefficients (P_{eff} ; cm/sec) of NBV obtained from perfusion of rat ileum (mean \pm SD; n=6).

$p > 0.05$; NBV vs NBV in tablet

* $p < 0.05$; NBV vs Unloaded SLN+NBV and NBV loaded SLN

** $p < 0.05$; Unloaded SLN+NBV vs NBV loaded SLN

3. CONCLUSION

In this study, NBV loaded SLNs were successfully applied for determination of their permeation behaviour via *in situ* SPIP studies. Results show that PEG modified SLN can be used to enhance oral absorption of NBV, and SLNs alone can be used as permeation enhancer in oral drug delivery. However, there is still a need for the clarification of the mechanism for enhanced oral bioavailability, especially for lipid based colloidal systems.

4. MATERIALS AND METHODS

4.1. Materials

Metoprolol tartrate was donated from Novartis (Novartis Drug Co., Turkey). Ingredients of golytely solution (NaCl, KCl, Na_2SO_4 , NaHCO_3 and mannitol) and ortho-phosphoric acid were supplied from Sigma-Aldrich (Germany). Phenol red was from Merck (Germany). Purified water (18 $\text{M}\Omega/\text{cm}$) was obtained by using New Human Power I water purification system (Korea). Poloxamer[®] 188 (Pluronic F68) was donated by BASF (Germany). Compritol[®] 888 was a kind gift from Gattefossée (France). NBV was from Sigma (Germany). PEG stearate (Simulsol M52) was obtained from Seppic (France). Soybean lecithin was supplied from Applichem (Germany). High pressure liquid chromatography (HPLC) grade acetonitrile was obtained from Sigma (Germany). All other chemicals and solvents were of HPLC or analytical reagent grade.

4.2. Preparation of SLNs

SLNs were obtained with high shear homogenization followed by high pressure technique optimized in our previous study [17]. Compritol 888 was used as lipid, lecithin and poloxamer 188 were employed as surfactant. The lipid phase (100 mg Compritol, 10 mg lecithin and 100 mg PEG) was melted at 70-80°C. The aqueous phase (100 mg poloxamer) was dissolved in 15 mL ultrapure water and heated to the same temperature as the lipid phase. Under homogenization at 24.000 rpm for 5 min with Ultra Turrax (T25, Ika Germany), the aqueous phase was transferred into the lipid phase. This mixture was dispersed in 10 mL ultrapure water at 4°C. To improve particle size distribution, high pressure homogenizer (Microfluidizer / ML110L) was used at 500 bars for 1 cycle after SLNs were prepared with high shear homogenizer. For preparation of drug loaded SLNs and drug loaded modified SLNs, 1.5 mg NBV was mixed with the lipid phase, melted together and prepared with the method as described above.

4.3. Characterization of SLNs

The average particle size and PDI of NBV loaded SLNs were measured using dynamic light scattering method (Malvern Zetasizer Nano ZS, Malvern Instruments, U.K.) at an angle of 173° at 25°C. Before starting to the experiment, the samples were diluted with ultrapure water to have an appropriate scattering intensity. The viscosity of water was chosen as 0.0089 cp. The measurements were performed five times at 25°C.

Plain folded capillary zeta cells (Malvern Zetasizer Nano ZS) was used for measurement of zeta potential. Electrophoretic mobility using Helmholtz–Smoluchowski Equation under an electrical field of 40 V/cm was used to calculate the zeta potential of the samples. All measurements were repeated five times at 25°C.

To evaluate the entrapment efficiency (EE %), SLN and the free drug were separated by using ultracentrifugation. The non-encapsulated (free) NBV was determined by HPLC method. Following equation was used for estimation of EE%.

$$EE \% = \frac{\text{Total amount of NBV} - \text{Free NBV}}{\text{Total amount of NBV}} \times 100 \quad (\text{Eq. 1})$$

One mL of NBV loaded SLN formulation (0.06 mg/mL) was added in a dialysis bag (Spectro/por Dialysis Membrane, molecular weight cut-off of 12-14 kDa), placed in a centrifuge tube containing 9 mL of ultrapure water, and then centrifuged at 55.000 rpm for 1.5 h (Beckman Coulter L100 XP-USA). Experiments were performed three times at 25±2°C. The water phase was filtered through a membrane filter (0.2 µm Nylon, Milipore Millex-GN) and the amount of NBV in ultrapure water was determined by a HPLC system equipped with a UV detector (Dionex Ultimate 3000, USA).

NBV was determined by a Thermo Scientific HPLC system with UV dedector and Thermo Scientific C18 column (25-cm long, 4.5 µm inner diameter) under the validated conditions: pH 3.0 acetonitrile:phosphate dihydrogen buffer (50:50, v/v) used as the mobile phase. Flow rate was adjusted to 1.0 mL/min, and wavelength was 220 nm. Volume of injection was 20 µl and the column temperature was kept at 40°C.

4.4. In situ studies

4.4.1. Preparation of perfusion medium

The perfusion medium was prepared using 40 mM Na₂SO₄, 10 mM KCl, 25 mM NaCl, 80 mM mannitol and 20 mM NaHCO₃. Ortho-phosphoric acid was used to adjust the pH of buffer to 7.4. Before each experiment, freshly prepared perfusion medium was filtered via 0.45 µm membrane filter.

4.4.2. Single-pass intestinal perfusion (SPIP) studies

Ethical permissions were obtained with 2014/A-61 protocol number from local ethic comitte (Committee of Use and Care of Animals, Inonu University), for animal studies. For intestinal perfusion studies, 200-300 g Sprague Dawley (female) rats were used. Before each experiment, animals were fasted for a period of 12-18 h but allowed to access to tap water. Animals were allocated one of the four groups given in Table 2.

Table 2. Details of experimental groups.

Groups	Content of Reservoir Solutions	
Group 1	Nebivolol (Pure)	10 µg/mL
	Metoprolol Tartrate	400 µg/mL
	Phenol Red	250 µg/mL
	Golytely Solution q.s	100 mL
Group 2	Nebivolol (Pure)	10 µg/mL
	Blank SLN	17 mL
	Phenol Red	250 µg/mL
	Golytely Solution q.s	100 mL
Group 3	NBV-SLN	17 mL
	Phenol Red	250 µg/mL
	Golytely Solution q.s	100 mL
Group 4	NBV powdered tablet	10 mg
	Metoprolol Tartrate	400 µg/mL
	Phenol Red	250 µg/mL
	Golytely Solution q.s	250 mL

In situ single pass intestinal perfusion test procedure used in this study was a modification of the previously published reports [21-25]. Under anaesthesia (60 mg/kg pentobarbital, intraperitoneal), the rats in a supine position were placed on an operation table at 37°C. The abdomen was opened by a 3-4 cm midline incision. After cannulation of ileal segment (7-10 cm) with flexible PVC tubings (outlet tubing id 1.70 mm and inlet tubing id 0.76 mm), it was attached to the perfusion system. Throughout the experiment, ileal segment moistened with saline, and covered with parafilm. The isolated ileal segment was rinsed for 10 minutes with blank perfusion solution (0.5 mL/min) using a peristaltic pump (Minipuls 3, USA). The exposed ileal segment was perfused with Golytely solution containing the substance, phenol red and metoprolol tartrate (reference compounds) at a flow rate of 0.2 mL/min for total period of 60 min.

In perfusion studies, metoprolol tartrate was used as a high permeability reference compound in order to compare the permeability coefficient of pure NBV and NBV in tablet. Phenol red was used as a zero permeability marker in all groups for correction of permeability coefficients of tested drugs for water transport [24]. Metoprolol tartrate was not used in group 2 and group 3 because NBV P_{eff} value in these groups (group 2 and group 3) was compared with the NBV P_{eff} values in groups 1 and 4.

The oral dose was taken as reference to determine the concentrations (0.01 mg/mL for NBV, 0.4 mg/mL for metoprolol tartrate and 0.25 mg/mL for phenol red). Outflow samples were obtained in every 10 minutes intervals to ependof tubes. The animals were sacrificed by cervical dislocation at the end of the experiments. Length of the perfused segment was noted.

4.4.3. Data analysis

P_{eff} was calculated after correcting measured C_{out}/C_{in} ratio for water transport (Equation 2) [25].

$$\frac{C'_{out}}{C'_{in}} = \frac{C_{out}}{C_{in}} \times \frac{C_{inphenolred}}{C_{outphenolred}} \quad (\text{Eq. 2})$$

Where $C_{inphenolred}$ and $C_{outphenolred}$ represent inlet and outlet phenol red concentrations, respectively. The plug flow model (Equation 3) was used for calculation of the P_{eff} values of the drug across the rat ileum [31]. In addition, k_a of the drug (NBV) was calculated using Equation 4 [32].

$$P_{eff} (cm / sec) = \frac{-Q \ln\left(\frac{C'_{out}}{C'_{in}}\right)}{2\pi RL} \quad (\text{Eq. 3})$$

$$k_a (1 / sec) = \frac{\left[1 - \left(\frac{C'_{out}}{C'_{in}}\right)\right] Q}{\pi r^2 L} \quad (\text{Eq. 4})$$

Flow rate (Q, mL/sec), corrected ratio of outlet to inlet concentration (C'_{out}/C'_{in}), length of the intestinal segment (L, cm), and radius of perfused ileal segment (R=0.2 cm) were used for calculation of P_{eff} [18, 22, 33, 34].

The inlet (C_{in}) and outlet (C_{out}) concentrations of phenol red were used to determine net water flux (NWF).

$$NWF = \frac{\left(1 - \left[\frac{C_{outphenolred}}{C_{inphenolred}}\right]\right)}{L} \times Q_{in} \quad (\text{Eq. 5})$$

A positive NWF value (Eq. 5) indicates secretion of fluid into the segment, while a negative NWF value indicates fluid loss from the mucosal side (lumen)[31].

4.6. Statistical analysis

All results were given as mean \pm standard deviation (SD). For multiple comparison, Kruskal-Wallis test was used. Two tailed non-parametric Mann-Whitney U test was used for two-group comparisons when appropriate, in order to determine differences between the experimental groups. Less than 0.05 *p* value was considered as significant.
