Treatment

ABSTRACT

The European Society for Clinical Microbiology and Infectious Diseases, the European Confederation of Medical Mycology and the European Respiratory Society Joint Clinical Guidelines focus on diagnosis and management of aspergillosis. Of the numerous recommendations, a few are summarized here. Chest computed tomography as well as bronchoscopy with bronchoalveolar lavage (BAL) in patients with suspicion of pulmonary invasive aspergillosis (IA) are strongly recommended. For diagnosis, direct microscopy, preferably using optical brighteners, histopathology and culture are strongly recommended. Serum and BAL galactomannan measures are recommended as markers for the diagnosis of IA. PCR should be considered in conjunction with other diagnostic tests. Pathogen identification to species complex level is strongly recommended for all clinically relevant *Aspergillus* isolates; antifungal susceptibility testing should be performed in patients with invasive disease in regions with resistance found in contemporary surveillance programmes. Isavuconazole and voriconazole are the preferred agents for first-line treatment of pulmonary IA, whereas liposomal amphotericin B is moderately supported. Combinations of antifungals as primary treatment options are not recommended. Therapeutic drug monitoring is strongly recommended for patients receiving posaconazole suspension or any form of voriconazole for IA treatment, and in refractory disease, where a personalized approach considering reversal of predisposing factors, switching drug class and surgical intervention is also strongly recommended. Primary prophylaxis with posaconazole is strongly recommended in patients with acute myelogenous leukaemia or myelodysplastic syndrome receiving induction chemotherapy. Secondary prophylaxis is strongly recommended in high-risk patients. We strongly recommend treatment duration based on clinical improvement, degree of immunosuppression and response on imaging. **A.J. Ullmann, Clin Microbiol Infect 2018;24:1**

Introduction

This is the third fungal diagnosis and management clinical guideline published in cooperation with various European scientific societies [1–9]. This part of the guideline regarding invasive and chronic aspergillosis is a condensation of all the recommendations

made by the guideline subcommittees and is presented in tables for easier and faster reading. More details on how the recommendations were arrived at are planned in supplementary publications. This *Aspergillus* guideline will follow the style of other guidelines by including diagnostic and therapeutic guidance. Other scientific groups have published guidelines on this topic previously and all

follow the common goal to provide clinicians with best guidance in their everyday working environment. Our goal was to provide a comprehensive European guideline focusing on the life-threatening diseases caused by *Aspergillus* spp.

Methods

Author panel recruitment and organization was similar to what was done previously [10]. In brief, experts in the field were nominated by the three societies: European Society for Clinical Microbiology and Infectious Diseases (ESCMID), the European Confederation of Medical Mycology (ECMM) and the European Respiratory Society (ERS). The total of 53 authors were grouped into their special fields of expertise. Subgroup coordinators were responsible for the first draft of recommendations. There were two face-to-face meetings followed by numerous electronic exchanges. Some of the first recommendations were presented at ECCMID 2014. This summary was reviewed and approved by all authors and sent to the ESCMID guideline director for public review. Then the final version was submitted to *Clinical Microbiology and Infection* for additional peer review and subsequent publication. Only the rationale of the chronic pulmonary aspergillosis (CPA) guideline was published ahead of time [11].

Questions were predefined and modified where appropriate and the strength of recommendation and quality of evidence was slightly modified (Table 1) [12]. Diagnostic tests are regarded as interventions.

Summary of recommendations

Diagnostic procedures

Early diagnosis of invasive aspergillosis (IA) is a challenge and should be based on the integration of clinical, radiological and microbiological data.

Table 1
Strength of recommendation and quality of evidence

Strength of recommendation	Definition
Grade A	Societies strongly support a recommendation for use
Grade B	Societies moderately support a recommendation for use
Grade C	Societies marginally support a recommendation for use
Grade D	Societies support a recommendation against use
Quality of evidence	Definition
Level I	Evidence from at least one properly* designed randomized, controlled trial (oriented on the primary end point of the trial)
Level II	Evidence from at least one well-designed clinical trial (including secondary end points), without randomization; from cohort or case–controlled analytic studies (preferably from more than one centre); from multiple time series; or from dramatic results of uncontrolled experiments
Level III	Evidence from opinions of respected authorities, based on clinical experience, descriptive case studies, or reports of expert committees
Added index	Source of Level II evidence
r	Meta-analysis or systematic review of randomized controlled trials
t	Transferred evidence, i.e. results from different patients' cohorts, or similar immune-status situation
h	Comparator group: historical control
u	Uncontrolled trials
a	Published abstract presented at an international symposium or meeting

* Poor quality of planning, inconsistency of results, indirectness of evidence etc. would lower the Strength of recommendation.

Thoracic imaging

In patients at risk for IA with fever of unknown origin or clinical symptoms of lower respiratory tract infection who remain febrile despite broad-spectrum antibacterial treatment, thin-section chest computed tomography (multidetector (MDCT), multislice (MSCT), spiral CT, high resolution CT) at optimized dose (according to the ALARA ('As Low As Reasonably Achievable') principle) is the imaging modality of choice (**AII**) [13–23]. Pulmonary CT angiography may be of interest in the early diagnosis of IA by depicting directly vessel occlusion at the level of a suspicious fungal lesion with a potential high negative predictive value regarding imaging evaluation [24–26], and is required in case of haemoptysis (**AII**). In selected patients where CT is not wanted or not feasible, magnetic resonance imaging (MRI) of the lungs may represent an alternative imaging to thin-section MSCT [27–32], positron emission tomography-CT being of modest interest in the diagnostics of IA [33,34].

No CT scanning technique is 100% sensitive or specific for pulmonary IA [35–37]. Classical CT findings of angioinvasive aspergillosis include macronodule(s) >1 cm, which may be surrounded by a halo of ground-glass attenuation (halo sign, early phase, inconstant) [36,38–40], pleural based wedge-shaped areas of consolidation [41], alveolar consolidations [36,42,43], masses (especially in solid organ transplant (SOT) recipients) [15,38], internal low attenuation [44], reverse halo sign [45], cavity or air-crescent sign (delayed finding), ground glass opacities and pleural effusion [17,35,46]. Bronchoinvasive forms may appear as tracheal or bronchial wall thickening, centrilobular nodules with tree in bud appearance [14] in a patchy distribution, predominant peribronchial areas of consolidation [47] or bronchopneumonia [46] (Table 2).

Bronchoalveolar lavage and biopsies

Other diagnostic procedures include early bronchoalveolar lavage (BAL) (**AII**) [48–54], guided by CT findings [55,56], and less frequently CT-guided transthoracic biopsies, video-assisted thoracoscopic surgery, open lung biopsies, transbronchial biopsies or convex endobronchial ultrasound transbronchial needle aspiration, the latter technique appearing to be a promising procedure in this setting [28,57–72]. Contraindications to these techniques need to be considered.

Imaging of other sites

Moreover, according to clinical symptoms, paranasal CT, CT or MRI of the central nervous system (CNS) as well as abdominal CT may also be required. In particular, findings of sinusitis with bone erosion may be observed, intracranial and/or intraorbital extension of the disease being best evaluated by MRI [73–75]. In the brain, due to direct spread from paranasal sinuses or haematogenous dissemination, meningeal enhancement or empyema, cerebral abscess, mycotic aneurysms as well as haemorrhagic lesions and rarely stroke may be seen [76–79].

Microscopy and culture

Both microscopy and culture should be attempted on appropriate specimens from patients at risk for IA (**AII**) with a priority for culture in most cases where insufficient material is available. Demonstrating tissue invasion by hyphae through microscopic examination of biopsy or autopsy material provides a diagnosis of proven invasive fungal infection. However, the sensitivity of microscopy for IA is 50% at best [80]. Specimens may be examined as a wet mount preparation with or without the addition of 10%

Table 2
Recommendations for imaging and bronchoalveolar lavage

Population	Intention	Intervention ^a	SoR	QoE	Comment	Ref.
Neutropenia, fever or clinical symptoms of pneumonia, empiric antibiotics failing to achieve defervescence, e.g. FUO	To detect pulmonary infiltrates	Chest CT and thin section multi-detector CT (MDCT)	A	II	Dose optimization recommended	[21,31,35,366]
	To identify vessel occlusion	Chest angio-CT/pulmonary CT angiography	B	II		[24–26]
Haemoptysis	To identify vessel erosion	Chest angio-CT/pulmonary CT angiography	A	II		[367,368]
Any, with infiltrate	To identify possible underlying fungal or other infectious disease	BAL	A	II		[21,49–54]
Any, with infiltrate	To obtain appropriate specimens for microscopy, culture and PCR	CT-guided BAL	A	III		[55,56]

^a Diagnostic tests are interventions.

potassium hydroxide. Fluorescent dyes such as Calcofluor White™ or Blancophor™ have the advantages of increased sensitivity, rapid turnaround time and broad applicability but are not specific for *Aspergillus* (AII). Gomori's methenamine silver stain (GMS) and periodic acid-Schiff (PAS) can be applied to histological sections and smears and should be conducted in all cases in which IA is considered a possibility (Table 3). Respiratory secretions from patients with suspected aspergillosis must be processed rapidly for culture to prevent overgrowth by bacteria and yeasts. To achieve optimal recovery of *Aspergillus* from BAL fluid, centrifugation of the sample is advised with investigation of the sediment (AIII). It is recommended that cultures of high volume untreated sputum and BAL should be performed as opposed to culturing small volumes of digested, liquefied samples [81] (Table 4). Specific media to support fungal growth are recommended. Species identification to the

complex level should be carried out for clinically relevant isolates from patients who need antifungal treatment, and for epidemiological purposes (AIII) (Table 5).

Non-culture based assays

Galactomannan (GM) detection in fluids (especially BAL) is more sensitive than culture for diagnosis of IA. GM is reported as optical density index (ODI). In serum samples an ODI cut-off of 0.5 results in high sensitivity in haematological patients in the absence of mould-active prophylaxis (AI) (Table 6). Serial screening for serum GM in prolonged neutropenia and in allogeneic stem cell transplantation recipients during the early engraftment phase has a high sensitivity and negative predictive value for IA (AII) [82]. Serial screening is not recommended in patients on mould-active prophylaxis [83].

Table 3
Microscopic examinations

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Any	To identify fungal elements in histological sections and stains	Histological examination Gomori's methenamine silver stain Periodic acid–Schiff	A	III	Histopathology is an essential investigation Inability to definitively distinguish other filamentous fungi GMS: removes cellular background; more sensitive to hyphal elements PAS: advantage of counter stain to check cellular detail	[61,80,369,370]
Any	To identify fungal elements in histological sections and stains	Fluorescent dyes: Calcofluor white™, Uvitex 2B, Blancophor™	A	II	Not specific to <i>Aspergillus</i> but high sensitivity and the micromorphology may provide information on the fungal class (e.g. <i>Aspergillus</i> : typically dichotomous and septate, Mucorales: pauci-septate and 90° angle branching, yeast: budding) Rapid turnaround time Broad applicability May be applied to frozen sections, paraffin-embedded tissue	[371–375]
Any	To identify fungal elements in histological sections and stains	Immunohistochemistry Monoclonal antibody WF-AF-1 or EB-A1 <i>In situ</i> hybridization	B	II	Have the potential to provide genus- and species-specific data Commercially available monoclonal antibodies WF-AF-1 is specific for <i>Aspergillus fumigatus</i> , <i>Aspergillus flavus</i> , and <i>Aspergillus niger</i> Time consuming and not broadly available	[371–375]
Any	To identify fungal elements in fresh clinical specimens (e.g. BAL)	Application of fluorescent dyes Calcofluor white™ or Uvitex 2B or Blancophor™	A	II	Essential investigation Not specific for <i>Aspergillus</i> species High sensitivity Rapid turn-around time Broad applicability No species identification but the micromorphology may provide information on the fungal class (e.g. <i>Aspergillus</i> : typically dichotomous and septate, Mucorales: pauci-septate and 90° angle branching, yeast: budding)	[61,80,376]

Abbreviations: BAL, bronchoalveolar lavage; CNS, central nervous system; GMS, Gomori's methenamine silver stain; HE, haematoxylin-eosin; PAS, Periodic acid–Schiff; QoE, Quality of evidence; SoR, Strength of recommendation.

Table 4
Sample selection and pre-analytical respiratory sample treatment

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Any	To achieve a homogeneous sample of viscous samples such as sputum	Liquefaction using a mucolytic agent, e.g. Pancreatin®, Sputolysin®, or using sonication and 1,4-dithiothreitol	A	III	Essential investigation High-volume sputum culture (entire sample) shown to significantly increase recovery	[81,377]
Any	To achieve optimal recovery of <i>Aspergillus</i> from BAL by centrifugation and investigation of the sediment	Centrifugation of BALs or bronchial aspirates	A	III	Essential investigation Isolation of <i>Aspergillus</i> dependent on volume cultured	[81]

Abbreviations: BAL, bronchoalveolar lavage; PCR, polymerase chain reaction; QoE, Quality of evidence; SoR, Strength of recommendation.

Table 5
Culture and *Aspergillus* species identification

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Any	Primary isolation from deep sites samples (e.g. biopsies, blood, CSF)	Culture on SDA, BHI agar, PDA at 30°C and 37°C for 72 h	A	III	Blood inhibits conidiation; BHI can help to recover some isolates; isolation of several colonies or isolation of the same fungus from a repeat specimen enhance significance	[81,378,379]
	Primary isolation from non-sterile samples, e.g. sputum, respiratory aspirates	Culture on SDA, BHI agar, PDA with gentamicin plus chloramphenicol at 30°C and 37°C for 72 h	A	III	High-volume sputum culture (entire sample) shown to significantly increase recovery; quantitative cultures are not discriminative for infection or colonization	
	Identification of species complex	Macroscopic and microscopic examination from primary cultures	A	II	Colony colour, conidium size, shape and septation. Colour of conidia and conidiophore and conidiogenesis (tease or tape mounts are preferred); expertise needed for interpretation	
	Identification of species complex (and species identification of <i>A. fumigatus</i> specifically)	Culture on identification media at 25–30°C, 37°C and 50°C (2% MEA and Czapek-Dox Agar) and microscopic examination	A	II	Thermotolerance test (growth at 50°C for species confirmation of <i>A. fumigatus</i>)	
	Identification at species level	MALDI-TOF MS identification	B	II	In-house databases are often used to improve identification rates	[380–383]
	Identification at species level	Sequencing of ITS, β -tubulin and calmodulin	A	III	Not necessary in organisms with typical growth, but in cases of atypical growth	[384,385]
	To study outbreaks	Microsatellite and CSP analysis	C	II	To study outbreaks (which in general may comprise more than one genotype)	[386–388]
			B	II	To study colonization patterns	[389]

Abbreviations: BHI, brain–heart infusion; CSF, cerebrospinal fluid; CSP, cell surface protein; ITS, internal transcribed spacer; MALDI-TOF MS, matrix-assisted laser desorption/ionization time-of-flight mass spectrometry identification; MEA, malt extract agar; PDA, potato dextrose agar; QoE, Quality of evidence; SDA, Sabouraud dextrose agar; SoR, Strength of recommendation.

Table 6
Galactomannan testing in blood samples

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Patients with prolonged neutropenia or allogeneic stem cell transplantation recipients not on mould-active prophylaxis	Prospective screening for IA	GM in blood ^a Draw samples every 3–4 days	A	I	Highest test accuracy requiring two consecutive samples with an ODI ≥ 0.5 or retesting the same sample Prospective monitoring should be combined with HRCT and clinical evaluation	[82,94,390–394]
			C	III		
Patients with prolonged neutropenic or allogeneic stem cell transplantation recipients on mould active prophylaxis	Prospective screening for IA	GM in blood ^a	D	II	Low prevalence of IA in this setting with consequently low PPV of blood GM test Prophylaxis may have a negative impact on sensitivity of the test or the low yield may be due to decreased incidence of IA	[395,396]
Patients with a haematological malignancy • Neutropenic patients • Non-neutropenic patients	To diagnose IA	GM in blood ^a	A	II	Significantly lower sensitivity in non-neutropenic patients	[319,391,397,398]
			B	II		
ICU patients	To diagnose IA	GM in blood ^a	C	II	Better performance in neutropenic than in non-neutropenic patients	[89,399]
Solid organ recipients	To diagnose IA	GM in blood ^a	C	II	Low sensitivity, good specificity Most data for lung SOT	[319,400,401]
Any other patient	To diagnose IA	GM in blood ^a	C	II	Piperacillin/tazobactam may no longer be responsible for false-positive results according to recent studies Cross-reactivity in case of histoplasmosis, fusariosis, talaromycosis (formerly: penicilliosis) False-positive results reported due to ingestion of ice-pops, transfusions, antibiotics, Plasmalyt® infusion	[398,402–409]
Cancer patients	To monitor treatment	GM in blood ^a	A	II		[85,353,410]

Abbreviations: GM, galactomannan; IA, invasive aspergillosis; ICU, intensive care unit; ODI, optical density index; PPV, positive predictive value; QoE, Quality of evidence; SoR, Strength of recommendation; SOT, solid organ transplantation.

^a Serum or plasma.

Table 7
Galactomannan testing in samples other than blood

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Any	To diagnose pulmonary IA	To apply GM test on BAL fluid	A	II	GM in BAL is a good tool to diagnose, optimal cut-off to positivity 0.5 to 1.0	[86,88,411–414]
Any	To diagnose cerebral IA	To apply GM test on cerebrospinal fluid	B	II	No validated cut-off	[415,416]
Any	To detect GM in tissue	To apply GM test on lung biopsies	B	II	Using a cut-off 0.5 resulted in a sensitivity of 90 % and a specificity of 95%; specimens need to be sliced, precondition for doing so is that sufficient material is available; dilution in isotonic saline	[61,417]

Abbreviations: BAL, bronchoalveolar lavage; GM, galactomannan; IA, invasive aspergillosis; QoE, Quality of evidence; SoR, Strength of recommendation.

Sensitivity of serum GM testing is significantly lower in non-neutropenic versus neutropenic patients [84]. Decrease of the ODI during the first 2 weeks of antifungal therapy is a reliable predictor of a satisfactory response in cancer patients [85]. GM detection in BAL specimens has an excellent performance with evidence that ODI of 0.5–1.0 has decreased predictive values compared with results of >1.0 [86] (**AII**) (Table 7). The test also has diagnostic value in patients undergoing lung transplantation or who are in intensive care [87–89]; a sensitivity of 100% and a specificity of 90.4% was defined at cut-off of 1.5 [87].

A constituent of the cell wall of many species and genera of fungi, (1-3)- β -D-glucan (BDG), is released into body fluids in association with fungal infection. A limited role is given for the exclusive testing of the BDG in diagnosing IA (**BII**) (Table 8); however, the combination with GM or PCR improves specific detection [90].

The *Aspergillus* lateral flow device assay can be performed on serum and on BAL samples, but at the time of writing this assay is not commercially available [91] (Table 9).

Aspergillus PCR has been applied mostly to blood and BAL fluid. For both sample types, a combination with other biomarkers increases the likelihood of IA [92,93]. The performance of serum PCR is not significantly different from that of whole blood [94–97]. Prospective screening of high-risk haematological patients by a combination of GM and PCR improves the diagnostic accuracy and is associated with an earlier diagnosis [98,99] (Tables 10 and 11).

Table 8
 β -D-glucan assays

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Mixed population: adult ICU, haematological disorders, SOT	To diagnose IFD	Diagnostic assay	C	II	Five different assays Overall sensitivity of 77% and specificity of 85% Specificity limits its value in this setting	[90,418]
		Screening assays	C	II	Two or more consecutive samples: sensitivity: 65%; specificity: 93% Studies included once to thrice weekly. Varies with assay and cut-off: Wako assay sensitivity: 40%–97%, specificity: 51%–99%	[90,418]
Adult haematological malignancy and HSCT	To diagnose IFD	Diagnostic assay	C	II	Overall sensitivity: 50%–70%, specificity: 91%–99%	[193–195,419–424]
ICU—mixed adult immunocompromised patients (haematology, SOT, cancer, immunosuppressive therapy, liver failure, HIV)	To diagnose IA	Diagnostic assay	C	II	Overall sensitivity: 78%–85%, specificity: 36%–75%, NPV: 85%–92% Specificity increased at higher cut-off values	[425,426]
ICU—mixed adult population: SOT, liver failure, immunosuppressed		Screening assays	C	III	Sensitivity: 91%, specificity: 58%, PPV: 25%, NPV: 98% Positive mean of 5.6 days before positive mould culture High false-positive rate in early ICU admission	[427]
Adult haematological malignancy and HSCT	To diagnose IA	Diagnostic assay	C	II	Overall sensitivity: 57%–76%, specificity: 95%–97%	[418,419,425]
		Screening assays	C	II	Overall sensitivity: 46%, specificity: 97% Confirmation with GM increases specificity Data suggest BDG is unsuitable for ruling out diagnosis of IA	

Abbreviations: BDG, β -D-glucan test; GM, galactomannan; HSCT, haematopoietic stem cell transplantation; IA, invasive aspergillosis; ICU, intensive care unit; IFD, invasive fungal disease; NPV, negative predictive value; PPV, positive predictive value; QoE, Quality of evidence; SoR, Strength of recommendation; SOT, solid organ transplantation.

On hyphal positive biopsy samples molecular detection of fungi is strongly recommended (**AII**). If no hyphae are visible the diagnostic yield of molecular methods is lower (Table 12). Recommendations for storage of original samples and isolates are given in Table 13. Antibody detection tests are not supported for the diagnosis of IA (**CII**) (Table 14).

Antifungal susceptibility testing

Resistance to antifungal agents is an increasing problem in *Aspergillus* diseases [100–102]. *Aspergillus* species can be intrinsically resistant to polyenes and azoles [103], or may acquire resistance following exposure to azole compounds [104]. Acquired resistance to azoles is mainly found in *Aspergillus fumigatus* and is reported globally [100,101,105–108]. Resistance may also develop through exposure to azole fungicides in the environment [109–112]. As resistant spores are present in ambient air, patients may present with azole-resistant *Aspergillus* disease without previous azole therapy [113,114]. Individual *Aspergillus* colonies from a single specimen may harbour different resistance profiles [117], hence multiple colony testing (up to five colonies) is recommended to increase sensitivity for azole-resistance detection (**BIII**).

In clinical laboratories, species identification to complex level is recommended for all clinically significant isolates (**BIII**). Some species are intrinsically resistant to either azoles or amphotericin B (Tables 5, 15–17).

Indications for testing for azole resistance in clinical *Aspergillus* isolates

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
All clinically relevant <i>Aspergillus</i> isolates (in patient groups or regions with known azole resistance)	Identify azole resistance	Reference MIC testing	A	II	In situations where rapid testing is available	[105,111,114,116,300,474–484]
Clinically relevant <i>Aspergillus</i> isolates in patient groups with high prevalence of azole resistance or patients unresponsive to treatment	Identify isolates with intrinsic resistance	Species identification to complex level	A	III	Some species are intrinsically resistant—e.g. <i>A. calidoustus</i> (azole resistant) and <i>A. terreus</i> (AmB resistant)	[103,485]
Clinically relevant <i>A. fumigatus</i> isolates	Identify azole-resistant <i>A. fumigatus</i>	Routine azole agar screening	B	III	Identifies resistant colonies that require MIC-testing	[118,486]
All isolates—resistance surveillance	Determine the local epidemiology of azole resistance	Periodical reference MIC testing of <i>A. fumigatus</i> complex	A	II	Test at least 100 isolates	[105,111,114,300,477–480,482–484]
Azole-resistant isolates	Determine nature and trends in Cyp51A mutation distribution	Cyp51A-gene mutation analysis	A	II	Test resistant isolates from surveillance survey	[107]

Abbreviations: AmB, Amphotericin B; MIC, minimum inhibitory concentration; QoE, Quality of evidence; SoR, Strength of recommendation.

Antifungal susceptibility testing of *Aspergillus* isolates should be performed in patients with invasive disease with the exception of azole-naïve patients in regions with no resistance found in contemporary surveillance programmes and regularly for epidemiological purposes including ≥ 100 isolates. This is particularly important in patients who are unresponsive to antifungal treatment, or in patients who are clinically suspected of having an azole-resistant pathogen (**AIII**) (Table 15). If MIC testing is not available, routine agar screening can be used to detect azole resistance

(Table 16) [118]. However, such isolates should be referred to a mycology reference laboratory for MIC testing. Clinical breakpoints for interpretation of azole and amphotericin B MICs against *Aspergillus* are currently available for the European Committee on Antimicrobial Susceptibility Testing (EUCAST) microdilution method but remain undetermined for Clinical & Laboratory Standards Institute (CLSI) methodology. Accordingly, EUCAST (**AII**) or CLSI broth microdilution methods (**BII**) can be used for determination of routine MICs for clinical guidance and for epidemiological

Any	To determine susceptibility to itraconazole	MIC (EUCAST/CLSI)	A	III	In general, a sensitive marker for azole resistance in <i>Aspergillus</i> ; test itraconazole and voriconazole as a minimum	[490,491,497–501]
Any	To determine susceptibility to voriconazole	MIC (EUCAST/CLSI)	A	III	Resistance/reduced susceptibility to other azole(s) may accompany that of voriconazole; isolated voriconazole resistance described related to TR ₄₆ mutation	[114,489,491,499–502]
Any	To determine susceptibility to posaconazole	MIC (EUCAST/CLSI)	B	III	Posaconazole resistance without itraconazole resistance not reported so far; current EUCAST breakpoint will misclassify approximately 15% susceptible isolates as I/R	[300,481,490,491,499–504]
Any	To determine susceptibility to isavuconazole	MIC (EUCAST/CLSI)	A	III	MIC often similar to voriconazole, but needs testing separately, if isavuconazole is to be used; lower MIC of isavuconazole as compared to itraconazole and voriconazole for <i>A. lentulus</i> and <i>A. udagawae</i> (<i>A. fumigatus</i> complex) (CLSI)	[490,499,500,502,505–507]

Abbreviations: CLSI, Clinical & Laboratory Standards Institute; EUCAST, European Committee on Antimicrobial Susceptibility Testing; MIC, minimum inhibitory concentration; QoE, Quality of evidence; SoR, Strength of recommendation.

resistance surveillance (**AII**). Both itraconazole and voriconazole (**AII**) should be tested to ensure detection of the voriconazole-resistance mutation TR₄₆/Y121F/T289A [118]. Posaconazole resistance without itraconazole resistance has not been reported (Table 17). EUCAST (**BIII**) or CLSI broth microdilution methods (**CIII**) can be used to determine amphotericin B MICs but although a correlation between MIC and clinical outcome exists for *Aspergillus terreus* and *Aspergillus flavus* it remains to be documented for *A. fumigatus* due to the scarcity of resistant isolates (Table 17).

Voriconazole and isavuconazole are recommended for the treatment of IA due to species showing high amphotericin B MICs (Table 18). Liposomal amphotericin B or amphotericin B lipid complex (ABLC) are recommended for species with intrinsic high azole MICs (Tables 19 and 20). In aspergillosis due to *A. fumigatus* specifically, voriconazole or isavuconazole are recommended if the isolate is voriconazole-susceptible (EUCAST MIC ≤ 1 mg/L) (**AI**). If resistant (voriconazole MIC >2 mg/L), liposomal amphotericin B therapy is recommended (**AIII_u**). It is unknown if patients infected with *A. fumigatus* with voriconazole MIC 2 mg/L (intermediate), respond less well to voriconazole monotherapy. These patients may have an increased probability of failing voriconazole monotherapy, and combination therapy with an echinocandin or liposomal amphotericin B monotherapy should be considered for invasive disease (**AIII**) (Table 20). In azole-resistant CPA, liposomal amphotericin B or micafungin can be considered (**BII**) if surgical intervention is precluded [11]. In settings with environmental azole resistance, no change to the primary regimen for IA is recommended when resistance rates are $<10\%$ (**AIII**). If azole resistance

rates are $>10\%$, first-line therapy with voriconazole plus echinocandin (**BIII**) or liposomal amphotericin B (**BIII**) is recommended.

Therapeutic drug monitoring

Patients with IA often have multiple conditions associated with their underlying disease and its treatment that affects the absorption, distribution, metabolism and clearance of antifungal medications [119]. As a result, standardized dosing recommendations for antifungals used in the prevention or treatment of IA may not achieve effective or safe drug exposures in all patients. Moreover, a subset of patients with severe infections or difficult to treat sites (e.g. CNS) or infections caused by *Aspergillus* spp. with elevated MICs may require higher drug exposures. Therapeutic drug monitoring (TDM) is often the most direct laboratory approach for identifying patients at jeopardy for treatment failure or toxicity because of inadequate or excessive drug exposures, and can be used to fine-tune antifungal dosing to improve the probability of optimal outcomes (Table 21).

Itraconazole

For itraconazole, a serum trough of 0.5–4 mg/L (measured by HPLC) is recommended for prophylaxis (**AII** (efficacy), **BII** (safety)) and a trough of 1–4 mg/L is recommended during the treatment of IA (**AII** (efficacy), **BII** (safety)) [120–125]. Itraconazole has an active metabolite, OH-itraconazole that is present in concentrations similar to those of the parent itraconazole compound (1:1) when

Table 18
Antifungal regimens in intrinsic resistance

patients are at pharmacokinetic steady state. OH-itraconazole concentrations may be reported separately when samples are analysed by HPLC or LC/MS/MS, but will be included in the overall report of 'itraconazole' concentrations if samples are analysed by bioassay [126,127]. Therefore, the target range for itraconazole is

higher when reported by bioassay (i.e. 3–17 mg/L) but may vary by laboratory depending on the reference standards used. Samples should be acquired within 5–7 days of starting therapy. Repeat TDM is recommended the following week to confirm that the patient remains in the therapeutic range, and repeated thereafter as

Table 21
Therapeutic drug monitoring

Clinical scenarios where antifungal therapeutic drug monitoring may be indicated	Examples, comments
Populations with increased pharmacokinetic variability	Impaired gastrointestinal function; hepatic dysfunction; children, elderly patients, obese patients, critically ill patients
Changing pharmacokinetics	Intravenous to oral switch, changing gastrointestinal function, changing hepatic or function, physiological-instability
Interacting medications	Patient receiving medication known to induce cytochrome P450 enzymes especially CYP3A4, antacids, proton-pump inhibitors (itraconazole capsules, posaconazole suspension), antiretroviral medications. Patients should have medication records screened using a drug interactions screening database before starting and stopping antifungals (example: www.fungalpharmacology.org , fungal-druginteractions.org , or http://www.aspergillus.org.uk/content/antifungal-drug-interactions)
Poor prognosis disease	Extensive or bulky infection, lesions contiguous with critical structures, central nervous system infection, multifocal or disseminated infection
Compliance concerns	Important issue with longer-term consolidation therapy or secondary prophylaxis in outpatient setting
Suspected breakthrough infection	Therapeutic drug monitoring can establish whether fungal disease progression occurred in the setting of adequate antifungal exposure
Suspected drug toxicity, especially neurotoxicity (voriconazole)	Exposure-response relationships are described for other toxicities (e.g. hepatotoxicity), the utility of therapeutic drug monitoring to prevent their occurrence is less well established

clinically indicated if there are changes in the patient's clinical condition, concomitant medications known to interact, or suspected toxicity (Table 22). Steady-state concentrations can often be predicted from earlier (non-steady) state samples through pharmacokinetic models or computerized dosage-assistance. In centres where these tools are available, sampling before day 5–7 may be preferable.

Voriconazole

A plasma trough concentration of 1–5.5 mg/L is considered adequate for most patients receiving voriconazole prophylaxis or treatment (AII, safety and efficacy) [128–133]. However, a trough of 2–6 mg/L (AII, safety and efficacy) is recommended in patients treated for severe infections (multifocal or disseminated disease, CNS infections, infection with pathogen with elevated MICs, e.g. an MIC of 2 mg/L) [130,131]. TDM is strongly recommended in children due to the much higher rates of drug elimination and potential for underdosing, especially with the lower voriconazole doses recommended in the past (AII) [134,135]. Plasma levels should be monitored between 2–5 days after initiation of therapy, and repeated the following week to confirm that the patient remains in the therapeutic range. Repeated monitoring is indicated until steady-state level in the therapeutic range is confirmed, if there are changes in the patient's clinical condition, concomitant medications, or suspected toxicity (Table 23).

Posaconazole

For patients receiving posaconazole suspension, a plasma trough of >0.7 mg/L is recommended during prophylaxis (BII, efficacy) [136,137]; and a trough of >1 mg/L is recommended if the patient is receiving treatment for suspected or documented IA (AII, efficacy) [138]. Currently, no studies have defined an upper plasma target that is associated with toxicity, although pharmacokinetic studies supporting the registration of the new posaconazole tablet and intravenous formulations with the EMA used a provisional cut-off of 3.75 mg/L [139–141]. Posaconazole plasma trough levels should be monitored on day 5 of therapy or soon thereafter, and repeated as clinically indicated.

For most patients prescribed posaconazole, we recommend using the newer tablet formulation (or intravenous formulation, if tablet formulation is contraindicated) rather than the suspension (AII), as tablets are more likely to consistently achieve target plasma levels and are less affected by gastrointestinally dependent drug interactions [139]. Currently, there is limited evidence to suggest that all patients receiving posaconazole tablets or intravenous formulation for prophylaxis require routine TDM; however, our opinion is that when treating suspected or documented *Aspergillus* infections, TDM could still be useful if the pathogen has elevated MICs, is unresponsive to treatment, or in the event of unexplained toxicity (BIII). Until further data are available, we recommend using TDM monitoring strategies and plasma trough

Table 22
Itraconazole therapeutic drug monitoring

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
All patients receiving itraconazole treatment for IA	Improve efficacy	Measure serum trough level on day 5 of therapy or soon after	A	II	Target itraconazole level >1 mg/L to 4 mg/L by HPLC. Hydroxy-itraconazole metabolite concentrations generally reported separately by HPLC or LC/MS/MS methods, but included in 'itraconazole' concentration report by bioassay. Therapeutic range by bioassay may vary by laboratory but typically fall in the range of (3–17 mg/L)	[122,127,535–537]
All patients receiving itraconazole for prophylaxis for IA	Improve efficacy	Measure serum trough level on day 5 of therapy or soon after	A	II	Target itraconazole level >0.5 mg/L (HPLC) or >3 mg/L (bioassay)	[124]
Patients receiving itraconazole	Reduce toxicity	Measure serum trough level on day 5 of therapy or soon after	B	II	Toxicity was associated with itraconazole levels >17.1 mg/L by itraconazole bioassay, which correspond to ~4 mg/L by HPLC	[127]

Abbreviations: HPLC, high performance liquid chromatography; IA, invasive aspergillosis; LC, liquid chromatography; MS, mass spectrometry; QoE, Quality of evidence; SoR, Strength of recommendation.

Voriconazole therapeutic drug monitoring

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
All patients receiving voriconazole treatment for IA	Improve efficacy, safety and compliance	Measure plasma trough level after 2–5 days of therapy or soon after	A	II	Target range of 1–5.5 mg/L	[128–131,133,538–540]
		Repeat plasma trough level	B	II	Repeat during second week of therapy, additional samples as clinically indicated and outlined in the text	[128–131,133,538–540]
All patients receiving voriconazole prophylaxis for IA	Improve efficacy, safety and compliance of prophylaxis	Measure serum trough level after 2–5 days of therapy or soon after, and 4 days after change of dose	A	II	As above; most studies investigated voriconazole treatment rather than prophylaxis	[132,541,542]
Patients with IA due to <i>Aspergillus</i> strains of reduced azole susceptibility MIC 2 mg/mL	Improve efficacy of treatment for isolates with MIC 2 mg/mL	Measure serum trough level after 2 to 5 days of therapy or soon after and 4 days after change of dose	A	II	Trough >2 mg/L recommended on the basis of PK/PD analysis	[131,543]

Abbreviations: IA, invasive aspergillosis; MIC, minimum inhibitory concentration; PK/PD, pharmacokinetic/pharmacodynamic; QoE, Quality of evidence; SoR, Strength of recommendation.

targets as detailed above and suggested for the suspension formulation (Table 24).

Isavuconazole

Although dose–response and plasma concentration–response relationships for isavuconazole have been reported in animal models, limited data are currently available to define a target therapeutic range or support the need for routine TDM for this agent [142]. Our opinion is that TDM could still be useful in the clinical assessment or monitoring of patients receiving isavuconazole therapy (CIII) if patients are unresponsive to treatment, have unexpected toxicity, pharmacokinetic drug–drug interactions, or if isavuconazole is being used to treat pathogens with elevated MICs or sanctuary sites such as the CNS. In the absence of well-defined therapeutic targets, documentation of a plasma trough in the range of 2–3 mg/L (mean concentration range from phase II/III clinical studies) after day 5 (including loading doses) suggests adequate drug exposure (Table 25).

Flucytosine

In rare circumstances, flucytosine may be used in combination with other antifungals for the treatment of triazole-resistant

Aspergillus spp. In this scenario, weekly measurements of peak serum concentrations 2 h following an oral dose (AII) are needed to confirm that peak concentrations are 50–100 mg/L to reduce the risk of toxicity. Trough concentrations required for efficacy are unknown but a level of 25–50 mg/L is recommended based upon experience from cryptococcosis [143,144].

Hospital environment

Standards for the hospital environment in immunosuppressed adults and children require special attention. Patients need to be segregated from construction or renovation (AII_h), potted plants (BII), and flowers in wards and in patients' rooms (CIII) [145–150]. Published data support the recommendation to accommodate patients in special hospital rooms with positive air pressure and HEPA filters (BII) or laminar airflow (BII_h). However, data were with historical controls, underpowered, or described by multivariate analysis describing high-risk situations for IA [151–154]. Protective masks for patients are proven not to be effective outside the protected area (CII) [155]. Filters for water supply, especially in showers, are recommended (BII) [156–160]. No data are available to support regular environmental air sampling to prevent infections. However, indoor sampling is advisable to monitor filter efficacy (BIII) [161,162].

Table 24
Posaconazole therapeutic drug monitoring

Population	Intention	Intervention	SoR	QoE	Comments	Ref.
Patients receiving posaconazole suspension for treatment of IA	Improve efficacy, compliance	Serum trough level on day 5 of therapy or soon after	A	II	Target level >1 mg/L. Gastroresistant tablet or intravenous formulation preferred for most patients, consider switch to tablet or intravenous, if no therapeutic levels with oral suspension. Repeat determination as clinically appropriate. Prolonged half-life gives similar results for random sampling and true trough samples	[138]
Patients receiving posaconazole suspension for prophylaxis to prevent IA	Improve efficacy, compliance	Serum trough level on day 5 of therapy or soon after.	C	II	Target level >0.7 mg/L. Adequate tissue concentrations may occur despite serum concentration <0.7 mg/L. Repeat determination as clinically appropriate	[136,137,544–547]
Patients receiving posaconazole	Improve safety	Measure serum trough level on day 5 of therapy or soon after	C	III	If treatment failure or toxicity suspected, therapeutic drug monitoring may be indicated in patients receiving gastroresistant tablet or intravenous formulation. Posaconazole exposures between 0.5–3.75 mg/L are well studied and considered safe and effective with all three formulations. Posaconazole plasma levels above this exposure range may be associated with toxicity	[120,121]

Abbreviations: IA, invasive aspergillosis; QoE, Quality of evidence; SoR, Strength of recommendation.

Treatment strategies

Two strategies are accepted for managing patients with haematological malignancy at risk for IA: (i) the patient receives primary prophylaxis or (ii) the patient receives no prophylaxis but is monitored at least twice weekly using biomarkers. The decision between the two strategies depends on local epidemiology, access to rapid diagnostics and patient characteristics. Breakthrough fungal diseases may appear through either symptoms or a disease-identifying biomarker or imaging result. Fig. 1 depicts a consensus algorithm for patient management.

Primary prophylaxis

At least three studies describe a number of patients who succumbed with IA missed before death [163–165]. Although diagnostic procedures have improved since then, they are not satisfactory. For this reason, patients known to be at high risk for IA may receive primary prophylaxis, especially patients with profound and prolonged neutropenia or with active graft-versus-host disease (GvHD) (Table 26).

Aspergillosis in haematological malignancy and haematopoietic stem cell transplantation

In patients treated for haematological diseases, prolonged severe neutropenia is the most important risk factor for the

development of IA. T-cell-depleted grafts, glucocorticosteroids and other immune suppressive drugs have been identified as further risk factors for IA in the later course after haematopoietic stem cell transplantation (HSCT), even in non-neutropenic patients [166]. In fact, up to two-thirds of patients with IA diagnosed after allogeneic HSCT are not neutropenic [167], and the median time of diagnosis of IA after allogeneic HSCT is 82 days (range, 3–6542 days) [168].

Treatment

Providing a definite diagnosis of IA is a continuously challenging endeavour for clinicians. The EORTC/MSG definitions are only designed for clinical studies. For clinical decision-making, these definitions could have a deleterious outcome as confirmation of a proven or probable diagnosis would delay the start of therapy [169]. Any patient at risk considered by the responsible clinician as having IA should receive antifungal therapy (AIII) (Tables 27 and 28). Physicians should consider switching from intravenous to oral therapy in stable and pharmacokinetically reliable patients. Treatment duration depends on clinical response and on immune reconstitution or recovery from GvHD. Good partial or complete remission requires no persistent clinical, including imaging (scarring allowed), or microbiological evidence of disease. The range of the duration of treatment (3 to >50 weeks) is huge and the evidence base to support any particular

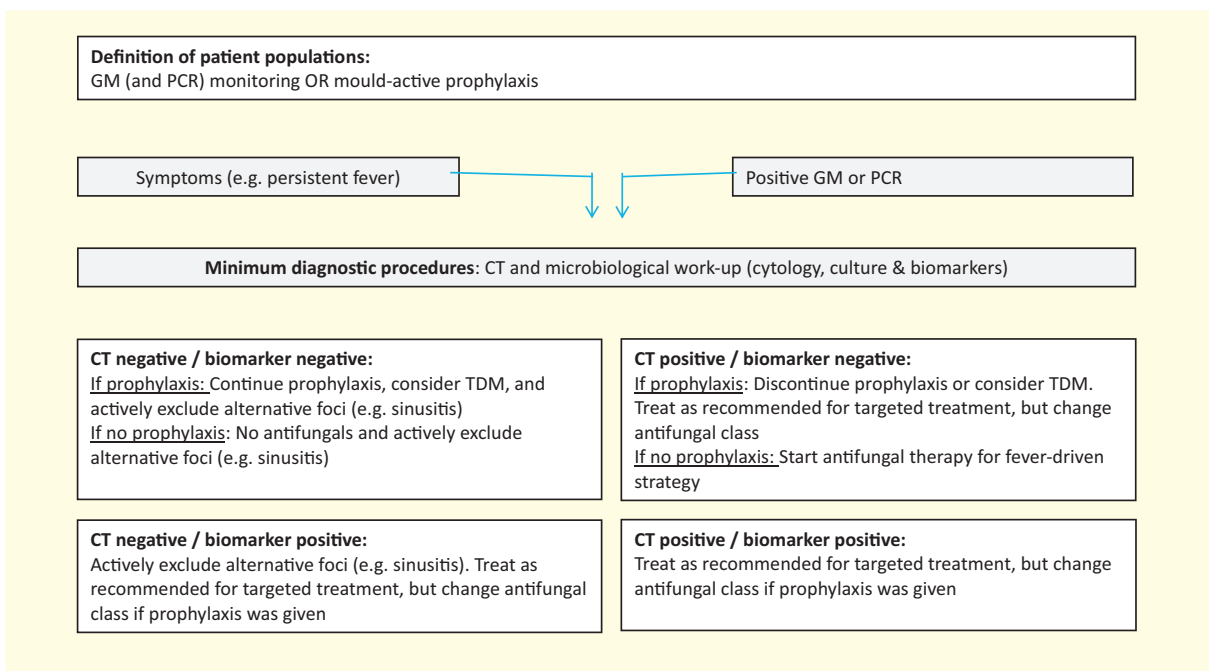

Fig. 1. Management during neutropenia.

Table 26
Primary prophylaxis

Population	Intention	Intervention	SoR	QoE	Comment	Ref.
Haematological malignancies, e.g. AML with prolonged and profound neutropenia	Lower incidence of IA	Posaconazole 200 mg tid suspension or 300 mg tablet qd	A	I	AML/MDS induction only. TDM especially with oral suspension. Tablets more bioavailable, bridging with posaconazole IV formulation possible	[548]
		L-AmB 12.5 mg 2 ×/weekly, nebulized, with undetermined dose of fluconazole	B	I	AML	[549,550]
		ABL3 3 mg/kg 3 ×/weekly	C	II _h	No difference to L-AmB regimen	[551]
		Micafungin 50 mg qd	C	II _t		[552,553]
		L-AmB 10 mg/kg q7d	C	II _u		[554]
		L-AmB 50 mg abs q2d	C	II _u		[555]
		L-AmB 15 mg/kg q14 d	C	II _u		[556]
		Voriconazole	C	II _t	Not better than fluconazole	[557]
Acute lymphoblastic leukaemia, remission induction chemotherapy	Lower incidence of IA	L-AmB 5 mg/kg biw	D	I	L-AmB more toxic than placebo, no significant reduction in IA rate	[561]
		Any mould active agent	D	III		No reference found.
Autologous HSCT or treatment of haematological malignancies besides acute leukaemia	Lower incidence of IA	Posaconazole 200 mg tid suspension or 300 mg tablet qd	B	II _t	Neutropenia duration approximately identical, TDM	[548]
		L-AmB 12.5 mg biw, nebulized, with fluconazole	B	II _t		[549]
		Voriconazole 200 mg bid	C	I	Not better than fluconazole, TDM	[557,562]
		Micafungin 50 mg/day	C	I	But no difference in subgroup analysis for aspergillosis	[552]
Allogeneic HSCT (until neutrophil recovery)	Lower incidence of IA	Itraconazole 400 mg/day oral solution	D	I	Toxicity issues; TDM	[549,560]
		Any antifungal agent	D	III	No study demonstrated outcome advantage	
Allogeneic HSCT (after neutrophil recovery and no GvHD)	Lower incidence of IA	Posaconazole 200 mg tid suspension or 300 mg tablet qd	A	I	TDM	[563]
		Voriconazole 200 mg bid	C	II	Not better than fluconazole; TDM	[557,562]
		Itraconazole 400 mg/day, oral solution	C	II	Toxicity issues; TDM	[560]
		Micafungin 50 mg/day	C	III	Only few patients with GVHD	[552]
Allogeneic HSCT (with moderate to severe GvHD and/or intensified immuno-suppression)	Lower incidence of IA	Posaconazole 200 mg tid suspension or 300 mg tablet qd	B	II _t	Neutropenia duration approximately identical; TDM	[548]
		Any other antifungal	D	III	No study demonstrated outcome advantage	
Allogeneic HSCT (until neutrophil recovery)	To reduce IA attributable mortality	Posaconazole 200 mg tid suspension or 300 mg tablet qd	B	II _t	Neutropenia duration approximately identical; TDM	[548]
		Any other antifungal	D	III	No study demonstrated outcome advantage	
Allogeneic HSCT (after neutrophil recovery, without GvHD)	To reduce IA attributable mortality	Posaconazole 200 mg tid suspension or 300 mg tablet qd	B	II _t	Neutropenia duration approximately identical; TDM	[548]
		Any other antifungal	D	III	No study demonstrated outcome advantage	
Allogeneic HSCT (with moderate to severe GvHD and/or intensified immuno-suppression)	To reduce IA attributable mortality	Posaconazole 200 mg tid suspension or 300 mg tablet qd	A	II	Mainly IFD-attributable mortality, TDM	[563]
		Any other antifungal	D	III	No study demonstrated outcome advantage	

Abbreviations: ABL3, amphotericin B–lipid complex; AML, acute myeloid leukaemia; bid, twice daily; GvHD, graft-versus-host disease; HSCT, haematopoietic stem cell transplantation; IFD, invasive fungal disease; L-AmB, liposomal amphotericin B; MDS, myelodysplastic syndrome; qd, once daily; QoE, Quality of evidence; SoR, Strength of recommendation; TDM, therapeutic drug monitoring; tid, thrice daily.

recommendation is weak [170–173]. Close monitoring (e.g. non-enhanced CT or, if applicable, biomarkers) is suggested once antifungal treatment is discontinued.

Additional adjunctive therapy such as the administration of granulocyte colony-stimulating factor (G-CSF) or G-CSF-primed granulocyte infusions (data mainly from paediatric populations) received only a weak supportive recommendation (CIII). In refractory cases, G-CSF (or interferon- γ) has immunomodulatory effects [174–179]. No controlled trials have been performed and only anecdotal data with small numbers of patients exist. Persistent neutropenia is related with treatment failure, recovery from neutropenia enhances the efficacy of antifungal agents. A recent Cochrane review investigating the efficacy of granulocyte transfusions indicated no mortality difference for any kind of infection in patients with neutropenia [180].

Fever-driven ('empiric'), and diagnosis-driven ('pre-emptive') therapy

As an alternative to prophylaxis, patients could receive the classical empirical administration of antifungal agents during fever refractory to broad-spectrum antibacterial agents. Empiric

treatment is defined as a fever-driven treatment approach. Patients who would qualify for this approach are patients receiving induction or remission chemotherapy for acute leukaemia or myelodysplastic syndrome or conditioning chemotherapy for HSCT. Empiric antifungal treatment is expected to reduce morbidity [181–186] and mortality [187,188] (Table 29). The duration of empiric antifungal treatment is set by the following rules applied in randomized clinical trials. If the patient is afebrile and has no active infection or infiltrates, then antifungal therapy can be discontinued after recovery of leucocyte counts [188–190]. Today, antifungal stewardship may warrant clinical trials on empiric treatment duration, but no such trial has been conducted so far.

Pre-emptive treatment is a diagnosis-driven strategy. In most cases, it is defined by positive GM testing. However, chest CT with pulmonary infiltrates could apply as well. The use of BDG and PCR testing as alternative biomarkers for GM have considerable merit [191,192], though BDG is not specific for *Aspergillus* disease. In haematological patients, false-positive BDG often results from contaminated infusions [193–196]. Very few authors wait for *Aspergillus*-associated suggestive radiological signs including nodule, halo sign, wedge-shaped area of consolidation, or—late in the course of invasive aspergillosis—the air crescent sign, before

starting antifungal treatment. Treatment choices are as recommended in targeted treatment.

Adult patients without haematological malignancy

Epidemiology

Approximately 43%–80% of the cases of IA appear in patients without a haematological malignancy [52,197–200], although these patients are rarely included in the seminal studies of antifungals [170,171,173]. The proportion of these patients is even increased when exposed to spore concentrations of >25 CFU/m³ in hospital air [201–204]. The non-haematological populations at risk

for IA include SOT recipients, patients treated with prolonged high-dose glucocorticosteroids, or with other immunosuppressants, patients with advanced AIDS or neoplasia, chronic obstructive pulmonary disease (COPD), liver failure, liver cirrhosis or influenza, as well as critically ill patients requiring admission to intensive care [52,197–199,205–208]. These patients frequently do not fulfil the EORTC/MSG criteria for invasive aspergillosis [169]. Confirmation of diagnosis may be delayed, resulting in high mortality rates. At the same time drug–drug interactions and toxicity can occur more frequently compared with haematological patients [52]. Physicians need to be aware of the specific risk factors, clinical manifestations and management challenges to improve outcome. In SOT recipients the average incidence of IA ranges from 0.1% to 11.6% [209,210],

Table 29

with the highest risk in small bowel (11.6%) and lung (8.6%) transplant recipients, followed by patients receiving liver (4.7%), heart (4.0%), pancreas (3.4%) and kidney (1.3%) grafts [209–211]. Half the cases will occur in the first 3 months after transplantation, in patients with post-surgical risk factors. Late aspergillosis is more common in elderly recipients, and patients with pronounced immunosuppression due to rejection or post-transplant neoplasia or chronically impaired graft function [210,212]. With the exception of lung transplantation, in which universal prophylaxis is still common, antifungal prophylaxis will target SOT recipients with additional risk factors [211]. Risk factors for early IA in all SOT recipients—including heart transplants—comprise renal failure requiring replacement therapy, re-intervention, cytomegalovirus disease, and high environmental exposure to mould spores [211,213–215]. In liver transplantation, a high model for end-stage liver disease (MELD) score, transplantation in fulminant hepatic failure, high intraoperative transfusion needs or re-transplantation are considered indications for post-surgical prophylaxis [216–224]. In lung transplant recipients, risk factors include previous respiratory tract colonization with *Aspergillus*, single lung transplant, CMV disease and acquired hypogammaglobulinaemia [225–227]. In kidney transplantation risk factors include COPD, delayed graft function, bloodstream infection and acute graft rejection [228] and a >1.25 mg/kg/day average dose of prednisone [229]. Finally, some polymorphisms in defence genes have also been suggested to increase risk in transplant recipients [230,231].

The incidence of IA in HIV patients has decreased since the advent of new antiretroviral therapy (2.2 cases per 10 000/year), but mortality remains high (38%) [232]. IA typically appears in patients with low CD4 counts and associated conditions such as neutropenia, advanced cirrhosis, liver transplantation or glucocorticosteroid therapy [233–241]. As in other non-haematological populations, EORTC/MSG criteria only detect half of the IA cases diagnosed among HIV-infected patients [232] and in a recent series of autopsies of AIDS patients, only 12% of the patients with IA had been diagnosed ante mortem [242] (Table 30).

Invasive aspergillosis may affect 0.3% of patients with liver cirrhosis [243]. Both acute liver failure and advanced cirrhosis, mainly alcoholic hepatitis treated with glucocorticosteroids, have been recognized as risk factors for IA [205,244–246]. A low level of clinical suspicion explains that 53% of the cases of IA in cirrhotic patients are only recognized post-mortem [247] and that liver disease is independently associated with IA-related mortality [199,248].

Invasive aspergillosis has also been described in apparently immunocompetent patients in a critical condition as a complication of acute respiratory distress syndrome, COPD, influenza, pneumonia, burns, severe bacterial infection, surgery and malnutrition. Incidence is 4 to 6/1000 intensive care unit admissions and the mortality is higher than 70% in most series [245,249–252]. Glucocorticosteroid treatment was the major host factor [253,254] and as in cirrhotic or HIV-positive patients delayed diagnosis is common [255,256]. Individuals with COPD requiring glucocorticosteroids represent a group with especially high mortality [249,257,258]. Risk factors include admission to an intensive care unit, chronic heart failure and antibiotic treatment and, above all, the cumulative dose of glucocorticosteroids [257].

Pulmonary and CNS aspergillosis predominates in these populations, but disseminated disease, fulminant and atypical forms may occur [203,214,225,251,259–267]. The sensitivity of most diagnostic methods is lower in non-haematological patients. Isolation of *Aspergillus* from respiratory cultures has a much lower positive predictive value so over-diagnosis has to be prevented [197,268–272]. Regarding imaging findings, angioinvasive presentation included in the EORTC/MSG criteria is uncommon in this setting [273]. Airway invasive radiological presentation was present in 37% of heart transplant recipients and was associated with delayed diagnosis and poorer prognosis [214,274]. In COPD and HIV-positive patients, the most common radiological presentation was an alveolar infiltrate [273,275,276]. Experience with biomarkers and PCR is still scarce in these populations, but the combination of at least two different methods appears to be the best diagnostic approach [277–285] (Table 31).

Treatment

Despite no comparative studies of antifungal therapy in non-haematological patients voriconazole remains the first option, as it has been related to reduced mortality [216,286–288] (Table 32). Combination therapy is uncommon, although retrospective data were encouraging in SOT recipients [289]. The risks of drug–drug interactions and toxicity are very important in these populations and TDM is advisable [290–295]. In patients with liver insufficiency, liposomal amphotericin B is usually the first therapeutic option. Antifungal resistance is not a common problem despite prophylaxis [296,297], although some cases have been reported [298–300]. Finally, immune reconstitution syndrome may occur after therapy initiation [301].

Most lung recipients receive antifungal prophylaxis. Targeted prophylaxis is preferred in the remaining SOT with risk factors [211,213,302–305]. However, significant variation in practice has been noted [221,304,306,307]. To avoid drug–drug interactions and toxicity, echinocandins or inhaled amphotericin are preferentially used [308–311], although voriconazole has also demonstrated its efficacy and safety in this setting [217,220,312–314]. Duration of prophylaxis is adjusted to the presence of risk factors and, with the exception of lung recipients, is usually limited to 3–4 weeks [215] (Table 33).

Special considerations in children

Presenting symptoms, distributions and patterns of diseases and vulnerability to IA are similar between children and adults. However, differences exist in epidemiology and underlying conditions, usefulness of newer diagnostic tools, pharmacology of antifungal agents and evidence from interventional phase III studies. Recommendations for paediatric patients are based on efficacy in phase II and III trials in adults, the availability of paediatric pharmacokinetic data, safety data and supportive efficacy data. In addition, regulatory approval is considered. Therapeutic drug monitoring is always recommended when mould-active azoles are used as prophylaxis or treatment.

Primary antifungal prophylaxis may be indicated in paediatric patients at ‘high risk’ for developing invasive fungal diseases, and specifically IA. An incidence rate of IFDs of $\geq 10\%$ is usually considered as high risk. High-risk populations include children with de novo or recurrent leukaemia (e.g. acute myeloid leukaemia, acute lymphoblastic leukaemia depending on treatment protocol), bone marrow failure syndromes with profound and persistent neutropenia (e.g. myelodysplastic syndrome, very severe aplastic anaemia), allogeneic HSCT recipients, patients with chronic granulomatous disease and those undergoing lung transplantation. For patients with haematological disorders, the mould-active oral

SOT Liver	Targeted ^a prophylaxis with echinocandins	To prevent IA	A	I	Standard dosed echinocandins reduced IA rate; duration of prophylaxis usually 21 days post SOT	[217,308,311,647]

Abbreviations: AmB, Amphotericin B; cAmB, conventional amphotericin B deoxycholate IA, invasive aspergillosis; QoE, Quality of evidence; SoR, Strength of recommendation; SOT, solid organ transplantation.

^a Targeted prophylaxis = only if additional risk factors; universal prophylaxis = to all patients in population.

azoles are the first choice to prevent IA in children, although neither itraconazole nor posaconazole are licensed for use in patients <18 years of age. Due to the lack of paediatric data, recommendations for lung and high-risk liver transplant patients correspond to those given for adults [213,315]. Secondary prophylaxis to prevent recurrence of IA when risk factors are persisting is recommended with an antifungal targeted at the previous *Aspergillus* species, which caused the first episode (see below and Table 34).

Diagnostic procedures used in children are not different from those used in adults but their performance may differ. Suggestive abnormalities (e.g. halo sign, air crescent sign) on chest CT as described in adults are less common in children in which non-specific masses or infiltrates predominate [316–318]. The GM test on blood and BAL samples have a similar sensitivity and specificity profile compared with adults [319–327]. The BDG test is not specific for *Aspergillus* and is not validated in children. Higher baseline levels are reported in healthy children and therefore the cut-off is unknown [328–332].

General management principles of IA are consistent with those in adults and include prompt initiation of antifungal therapy, control of predisposing conditions (e.g. reduction or discontinuation of glucocorticosteroids in immunosuppressed, administration of colony-stimulating factors in neutropenic patients), and surgical interventions on a case-by-case basis using a multidisciplinary approach. Voriconazole is recommended as the first-line agent to treat IA in all children except neonates (AIII). Liposomal amphotericin B is first choice for neonates (AIII) and may replace voriconazole as first-line treatment in areas or institutions with a high prevalence of azole-resistant *A. fumigatus*. Upon diagnosis of invasive pulmonary aspergillosis, thorough evaluation for further sites of infection is required and should include the CNS. The optimal duration of therapy is determined by the resolution of all signs and symptoms and reversal of the underlying deficit in host defences. For salvage therapy and breakthrough

infections, a switch to a different class of antifungals is recommended [123,132,138,170,171,177,333–341] (Table 35).

If a fever-driven (empiric) strategy is used in at risk paediatric haematological patients, caspofungin or liposomal amphotericin B is recommended until resolution of fever and neutropenia [342–344]. Treatment recommendations for a diagnosis-driven (pre-emptive) strategy correspond to those made for targeted treatment [185,186,345,346].

Secondary prophylaxis

Secondary prophylaxis is a treatment strategy to prevent recurrence of IA during a subsequent risk period of immunosuppression. Patients with a history of IA previously successfully treated with antifungals entering a subsequent risk period of immunosuppression, e.g. allogeneic HCT (early phase), chemotherapy resulting in severe neutropenia (i.e. <500/μL and at least for 7 days), acute GvHD >I° or extensive chronic GvHD, or T-cell-suppressing therapy, including steroids, are at risk. Agents for secondary prophylaxis are listed in Table 36.

Treatment of refractory disease

Refractory IA is defined as progression of disease and should be differentiated from stable disease [349]. Patients with radiological evidence of progression and persisting elevated GM have a very high probability of treatment failure resulting in death. Assessment of response should use composite outcome parameters including clinical, radiological and mycological criteria. Radiological progression following or closely preceding neutrophil recovery should be carefully evaluated and is not necessarily indicative of failure. Keeping this in mind, assessing the response 2 weeks after treatment initiation generally allows prediction of the response, especially recognizing oncoming failure [350]. In case of GM-negative

IA, early assessment of response may be difficult and could require a longer period of therapy. If failure is ascertained, look for poor vascular supply (i.e. sinusitis requiring surgical treatment), microbiological confirmation is recommended as identification of the fungus at the species level is pivotal. If a viable organism is recovered, susceptibility testing is recommended, especially regarding azole resistance. On the other hand, azole concentration should be monitored as well (see sections on resistance and therapeutic drug monitoring within this guideline) [38,85,349,351–357]. The choices of antifungal agents in refractory disease are listed in Table 37.

Chronic pulmonary aspergillosis

Chronic pulmonary aspergillosis is an indolent destructive disease of the lungs usually complicating other pulmonary conditions occurring in non- or mildly immunocompromised patients [358,359]. Its manifestations include chronic cavitory pulmonary aspergillosis (CCPA), which if left untreated may progress to chronic fibrosing pulmonary aspergillosis, *Aspergillus* nodule and single aspergilloma [11,360]. Subacute invasive pulmonary aspergillosis (previously chronic necrotizing pulmonary aspergillosis) is also a

cavitating destructive lung disease, usually found in moderately immunocompromised patients, which progresses more rapidly, typically over 1 to 3 months. The diagnosis of CPA requires a combination of characteristics: one or more cavities with or without a fungal ball present or nodules on thoracic imaging, either direct evidence of *Aspergillus* infection (culture or microscopy from biopsy) or an IgG antibody response to *Aspergillus* spp. and exclusion of alternative diagnoses (especially mycobacterial infection), all present for at least 3 months [11,361]. Over 90% of patients have circulating *Aspergillus* antibody (precipitins) (AII) [362]. A positive culture of *A. fumigatus* respiratory tract secretion (BAL, bronchoscopy aspiration) is not diagnostic because many different pathologies are attributable to the fungus, and it may be an airway-colonizing fungus or a plate contaminant in the laboratory.

If a fungal ball is seen, then only a positive test of *Aspergillus* IgG or precipitins confirms pathogenicity. Patients may have CPA and other infections concurrently (see below).

The distinctive hallmark of CCPA is new and/or expanding cavities with thick or thin walls in those with chronic lung disease. An intracavitary fungal ball may be present, often with pleural thickening and extensive parenchymal destruction and/or fibrosis. Patients may have CPA and other infections concurrently,

Abbreviations: ABPA, allergic bronchopulmonary aspergillosis; bid, twice daily; CCPA, chronic cavitary pulmonary aspergillosis; CNPA, chronic necrotizing pulmonary aspergillosis; CPA, chronic pulmonary aspergillosis; qd, once daily; QoE, Quality of evidence; SAIA, subacute invasive aspergillosis; SoR, Strength of recommendation; TDM, therapeutic drug monitoring.

especially bacterial including *Pseudomonas aeruginosa* infection or tuberculosis and non-tuberculous mycobacterial infection. *Aspergillus* nodules, which may be single or multiple, may mimic malignancy as well as nodules seen in rheumatoid arthritis, coccidioidomycosis, tuberculosis, non-tuberculous mycobacterial infection and, rarely, actinomycosis or rheumatoid arthritis. Typically, *Aspergillus* nodules appear rounded, some with low attenuation or cavitation within. Some are spiculated, a common feature of carcinoma [360].

If technically feasible, single aspergilloma should be surgically removed, preferably through a video-assisted thoracic surgery technique with due consideration for risks as recommended [363]. Long-term oral antifungal therapy is strongly recommended in patients with CCPA, partly to reduce general and respiratory symptoms [364,365], but also to minimize haemoptysis and prevent lung destruction and fibrosis (AII); itraconazole or voriconazole are effective for CCPA (AIII) [11]. Oral posaconazole is a potential alternative treatment (BII) [11]. Six months of therapy is the recommended minimum (AI) [11]. Relapse is common after discontinuation. Intravenous therapy for CPA is useful in patients who fail or are intolerant of triazoles or have triazole-resistant *A. fumigatus*. Prednisolone may be considered for underlying symptom control only if patients are adequately treated with antifungals. Mild and moderate haemoptysis usually responds to tranexamic acid; severe haemoptysis should be arrested with bronchial artery embolization (Table 38).

Conclusions

This executive summary is a comprehensive guideline covering many aspects of *Aspergillus* diseases. It provides guidance for clinicians on prevention of disease, diagnostic procedures, resistance issues and treatment of IA as well as CPA. The guideline group intends to provide additional publications supporting the rationale of the recommendations given.

Finally, the guideline group provides comprehensive tables explaining various options for specific situations.

Acknowledgements

Professor William Hope was a member of the TDM group; however, he stepped down during the process of guideline development due to his new post as guideline director of ESCMID to avoid any conflicts of interest. His contributions were very much appreciated to the entry guideline group. We are thankful for his help. We also thank Dr Vincent Dunet (Department of Diagnostic and Interventional Radiology, CHUV, Lausanne, Switzerland) and Dr Frédéric Lamoth (Department of Infectious Disease, CHUV, Lausanne, Switzerland) for their help and contribution to this guideline. We are indebted to Kerstin Albus, MSc, for her critical review and corrections of the manuscript.

Dr Brüggemann has received grants and consultancy fees as well as speaker fees from MSD, Pfizer, Gilead and Astellas. All contracts were with Radboudumc and all payments have been received by Radboudumc. Dr Buchheidt reports personal fees and non-financial support from Astellas, personal fees from Basilea, grants, personal fees and non-financial support from Gilead, personal fees and non-financial support from Merck Sharp & Dohme/Merck, grants, personal fees and non-financial support from Pfizer, outside the submitted work. Dr Cadranet reports personal fees from MSD, outside the submitted work. Dr Castagnola reports personal fees from Astellas Pharma, non-financial support from Gilead, outside the submitted work. Dr Chakrabarti has nothing to disclose. Dr Cuenca-Estrella reports grants and other from Gilead and MSD, grants from Amplyx, Cidara, Scynexis and F2G, other from Astellas, outside the submitted work. Dr Denning and family hold Founder shares in F2G Ltd, a University of Manchester spin-out antifungal discovery company. He acts or has recently acted as a consultant to Astellas, Sigma Tau, Basilea, Scynexis, Cidara, Biosergen, Quintiles, Pulmatrix, Pulmocid and Zambon. In the last 3 years, he has been paid for talks on behalf of Astellas, Dynamiker, Gilead, Merck and Pfizer. He is a longstanding member of the Infectious Disease Society of America Aspergillosis Guidelines group, the European Society for Clinical Microbiology and Infectious Diseases Aspergillosis Guidelines group and the British Society for Medical Mycology Standards of Care committee. In addition, Dr Denning has a patent Assays for Fungal Infection licensed. Dr Dimopoulos has nothing to disclose. Dr Fortún has nothing to disclose. Dr Gangneux reports grants and personal fees from Pfizer, MSD, Gilead and Astellas during the conduct of the study. Dr Garbino has nothing to disclose. Dr Groll reports grants and personal fees from Gilead, Merck, Sharp & Dohme and Pfizer, personal fees from Astellas and Basilea, outside the submitted work. Dr Heinz reports personal fees from Astellas, Gilead and Basilea, grants and personal fees from MSD Sharp & Dohme/Merck and Pfizer, outside the submitted work. Dr Herbrecht reports personal fees from Astellas, Basilea, Gilead, MSD and Pfizer, outside the submitted work. Dr Heussel reports personal fees from Boehringer Ingelheim, Novartis, Gilead, Intermune and Fresenius, grants from Siemens, Pfizer and Boehringer Ingelheim, lecture fees from Gilead, MSD, Pfizer, Intermune, Novartis, Basilea and Bayer, outside the submitted work. Dr Heussel has a patent for Method and Device For Representing the Microstructure of the Lungs licensed. Dr Kibbler reports personal fees from Gilead, outside the submitted work. Dr Klimko reports personal fees from Astellas and Pfizer, and grants and personal fees from Merck, outside the submitted work. Dr Kullberg reports personal fees from Astellas, Amplyx, Cidara, Gilead, Pfizer and Scynexis, outside the submitted work. Dr Lagrou reports grants, personal fees and non-financial support from MSD, Pfizer

and Gilead, personal fees from Abbott, outside the submitted work. Dr Lange reports personal fees from Chiesi, Gilead, Abbvie, MSD, Becton Dickinson, Janssen, Lucane, Novartis, Thermofisher and Transgene, outside the submitted work. Dr Lass-Flörl reports grants, personal fees and other from Astellas Pharma and Gilead, personal fees and other from Pfizer, other from Merck Sharp and Dohme and Basilea, outside the submitted work. Dr Lehrnbecher reports grants, personal fees and non-financial support from Gilead Sciences, personal fees and non-financial support from Astellas and Merck/MSD, personal fees from Basilea, outside the submitted work. Dr Lewis reports personal fees from Gilead, grants and personal fees from Merck, personal fees from Cidara, outside the submitted work. Dr Loeffler has nothing to disclose. Dr Lortholary has nothing to disclose. Dr Maertens reports grants, personal fees and non-financial support from MSD, Astellas, Pfizer and Gilead, personal fees and non-financial support from Basilea and F2G, personal fees from Scynexis, during the conduct of the study. Dr Marchetti has nothing to disclose. Dr Meis reports personal fees and grants for consultancy from Astellas, MSD and Scynexis, grants from F2G and Pulmozyme, personal fees and grants for lectures including service on speakers' bureaus from Merck, Gilead and TEVA, grants for travel and accommodation from Nordic-Pharma, outside the submitted work. Dr Muñoz has nothing to disclose. Dr Pagano reports grants and personal fees from Gilead, personal fees from MSD, Pfizer, Novartis, Janssen and Basilea, outside the submitted work. Dr Ribaud has nothing to disclose. Dr Richardson reports other from Associates of Cape Cod, personal fees from Gilead and MSD, other from Gilead, during the conduct of the study. Dr Roilides reports grants, personal fees and non-financial support from Astellas, Gilead Merck and Pfizer, outside the submitted work. Dr Ruhnke reports personal fees from Basilea and Scynexis for board membership, personal fees from Basilea and Janssen for lectures including service on speakers bureaus, personal fees from Janssen for development of educational presentation, outside the submitted work. Dr Sanguinetti has nothing to disclose. Dr Sheppard reports grants and personal fees from Merck, outside the submitted work. Dr Sinko reports personal fees (honoraria, fees for consulting, lectures, speakers bureaus) from Pfizer, Merck, Astellas. Dr Skiada has nothing to disclose. Dr Ullmann reports personal fees from Pfizer, Astellas, MSD and Gilead, outside the submitted work. Dr Vehreschild reports personal fees, non-financial support and other from Astellas, during the conduct of the study; grants and personal fees from Astellas and Merck/MSD, grants from Seres Therapeutics and DaVolterra, grants and personal fees from Gilead, personal fees from Berlin Chemie, Falk Foundation, Organobalance and Pfizer, outside the submitted work. Dr Verweij reports grants from Gilead Sciences, MSD and F2G, outside the submitted work. Dr Viscoli reports personal fees from MSD, Gilead, Pfizer, Angelini, Astellas and Basilea, outside the submitted work. Dr Warris reports grants from Gilead, other from Gilead and Basilea, outside the submitted work.

Appendix A. Supplementary data
